

H8/538F
HD64F5388
Hardware Manual

Preface

The H8/538F extends the field programmability of Hitachi's ZTAT™*1 family of microcontrollers, which have user-programmable on-chip ROM. The H8/538F is the first microcontroller in the F-ZTAT™*2 family, which has on-chip flash memory that can be programmed on-board.

The H8/538F is an original Hitachi high-performance single-chip microcontroller with a high-speed 16-bit CPU core and extensive on-chip peripheral functions. The H8/538 is suitable for controlling a wide range of medium-scale office and industrial equipment and consumer products.

The general-register architecture and highly orthogonal, optimized instruction set of the CPU enable even programs coded in the high-level C language to be compiled into efficient object code.

Many of the peripheral functions needed in microcontroller application systems are provided on-chip, including large RAM and ROM, a powerful set of timers, a serial interface, a high-precision A/D converter, and I/O ports. Compact, high-performance systems can be implemented easily using the H8/538F. On-chip flash memory enables the H8/538F to execute high-speed data transfers and high-speed computations.

This document describes the H8/538F hardware. For further details about the instruction set, refer to the *H8/500 Series Programming Manual*.

Notes: 1. ZTAT™ (Zero Turn-Around Time) is a trademark of Hitachi, Ltd.
2. F-ZTAT™ (Flexible-ZTAT) is a trademark of Hitachi, Ltd.

Section 1 Overview

1.1 Features

The H8/538F is an original Hitachi CMOS microcomputer unit (MCU) comprising a high-performance CPU core plus a full range of supporting functions—an entire system integrated onto a single chip.

The H8/500 CPU features a highly orthogonal instruction set that permits addressing modes and data sizes to be specified independently in each instruction. An internal 16-bit architecture and 16-bit, two-state access to both on-chip memory and external memory enhance the CPU's data-processing capability and provide the speed needed for realtime control applications.

The on-chip supporting functions include RAM, ROM, timers, a serial communication interface (SCI), A/D converter, and I/O ports. An on-chip data transfer controller (DTC) provides an efficient way to transfer data in either direction between memory and I/O without using the CPU.

H8/538 ZTAT™ (zero turn-around time) microcontrollers with user-programmable on-chip ROM are already available. The PROM of a ZTAT™ microcontroller, however, can be programmed only once. Flash memory can be programmed and erased electrically, enabling memory contents to be updated while the device is mounted on-board. Compared with EEPROM, flash memory offers higher integration density because it uses only one transistor instead of two.

On-chip flash memory enables internal programs and data to be updated even after the H8/538F has been installed in its application system. This opens up such possibilities as small-quantity, high-diversity production with quick turn-around, optimal tuning of individual units, and field maintenance and upgrades after shipment.

Table 1-1 lists the main features of the H8/538F.

Table 1-1 Features

Feature	Description												
H8/500 CPU	<p>General-register machine</p> <ul style="list-style-type: none">• Eight 16-bit general registers• Five 8-bit and two 16-bit control registers <p>High-speed operation</p> <ul style="list-style-type: none">• Maximum clock rate: 16 MHz <p>Two operating modes</p> <ul style="list-style-type: none">• Minimum mode: maximum 64-kbyte address space• Maximum mode: maximum 1-Mbyte address space <p>Highly orthogonal instruction set</p> <ul style="list-style-type: none">• Addressing modes and data size can be specified independently for each instruction <p>Register and memory addressing modes</p> <ul style="list-style-type: none">• Register-register operations• Register-memory (or memory-register) operations <p>Instruction set optimized for C language</p> <ul style="list-style-type: none">• Special short formats for frequently-used instructions and addressing modes												
Memory	<ul style="list-style-type: none">• 2-kbyte high-speed on-chip RAM• 60-kbyte flash memory (7 large blocks + 8 small blocks)

Table 1-1 Features (cont)

Feature	Description
16-bit integrated-timer pulse unit (IPU)	<p>Automatic measurement functions</p> <ul style="list-style-type: none"> • Programmable period counting • Phase counting <p>Synchronization function</p> <ul style="list-style-type: none"> • Counters on different channels can be synchronized
Serial communication interface (SCI)	<ul style="list-style-type: none"> • Asynchronous or clocked synchronous mode (selectable) • Full duplex: can send and receive simultaneously • On-chip baud rate generator • Multiprocessor communication function (asynchronous mode)
A/D converter	<ul style="list-style-type: none"> • Ten-bit resolution • Twelve channels, single mode or scan mode selectable • Can be triggered externally, or by IPU compare match • Selectable voltage conversion range
I/O ports	<ul style="list-style-type: none"> • 74 input/output pins • 12 input-only pins
Interrupt controller (INTC)	<ul style="list-style-type: none"> • Five external interrupt pins (NMI, $\overline{\text{IRQ}}_0$ to $\overline{\text{IRQ}}_3$) • Thirty-nine internal interrupt sources • Eight programmable priority levels
Data transfer controller (DTC)	<ul style="list-style-type: none"> • Can transfer data in both directions between memory and I/O without using the CPU
Wait-state controller (WSC)	<ul style="list-style-type: none"> • Can insert wait states (T_W) in access to external I/O or memory
Bus controller (BSC)	<ul style="list-style-type: none"> • Address space can be partitioned into 16-bit-bus and 8-bit-bus areas • Address space can be partitioned into two-state-access and three-state-access areas • I/O ports can be expanded and reconfigured
Operating modes	<p>Seven operating modes</p> <ol style="list-style-type: none"> 1. High-speed 16-bit bus modes, starting in 2-state 16-bit mode at reset <ul style="list-style-type: none"> • Expanded minimum mode (mode 1) • Expanded maximum modes (modes 3 and 4) 2. Low-speed 16-bit bus modes, starting in 3-state 8-bit mode at reset <ul style="list-style-type: none"> • Expanded minimum mode (mode 6) • Expanded maximum mode (mode 5) 3. Low-speed 8-bit bus mode <ul style="list-style-type: none"> • Expanded minimum mode (mode 2) 4. Single-chip mode <ul style="list-style-type: none"> • Minimum mode (mode 7)

(2) **Pin Functions:** Table 1-4 indicates the function of each pin.

Table 1-4 Pin Functions

Type	Symbol	Pin No.		I/O	Name and Function
		QFP-112	TFP-120		
Power	V _{CC}	1, 44, 76	2, 47, 81	Input	Power: Connected to the power supply (2.7 V to 5.5 V). Connect all V _{CC} pins to the system power supply. The chip will not operate if any V _{CC} pin is left unconnected.
	V _{SS}	10, 26, 35, 53, 73, 99	11, 27, 38, 56, 78, 106	Input	Ground: Connected to ground (0 V). Connect all V _{SS} pins to the 0-V system power supply. The chip will not operate if any V _{SS} pin is left unconnected.
Clock	XTAL	75	80	Input	Crystal: Connected to a crystal resonator having a frequency equal to the desired system clock frequency (ϕ). If an external clock is input at the EXTAL pin, input the reverse-phase clock at XTAL.
	EXTAL	74	79	Input	Crystal/external clock: Connected to a crystal resonator or external clock having a frequency equal to the desired system clock frequency (ϕ). See section 8.2, “Oscillator Circuit” for examples of connections of XTAL and EXTAL.
	ϕ	69	74	Output	System clock: Supplies the system clock (ϕ) to peripheral devices.
System control	BACK	68	73	Output	Bus request acknowledge: Indicates that the bus right has been granted to an external device. A device requesting the bus sends a BREQ signal to the H8/538F. The H8/538F replies with a BACK signal.
	BREQ	67	72	Input	Bus request: Sent by an external device to the H8/538F chip to request the bus right. Granting of the bus is indicated by the BACK signal.
	STBY	70	75	Input	Standby: Input pin for transition to the hardware standby mode (a power-down state).
	RES	71	76	Input	Reset: Input pin for transition to the reset state.

Table 1-4 Pin Functions (cont)

Type	Symbol	Pin No.		I/O	Name and Function
		QFP-112	TFP-120		
Address bus	A ₁₉ –A ₀	65–54, 52–45	70–62, 59–57, 55–48	Output	Address bus: Address output pins.
Data bus	D ₁₅ –D ₀	43–36, 34–27	46–39, 37–32, 29, 28	Input/ Output	Data bus: Sixteen-bit bidirectional data bus.
Bus control signal	WAIT	66	71	Input	Wait: Requests insertion of wait states (T _W) in external-device access cycles by the CPU; used for interfacing to low-speed external devices.
	AS	77	82	Output	Address strobe: Indicates valid address output on the address bus during external-device access.
	RD	78	83	Output	Read: Indicates reading of data from the data bus during external-device access. The CPU latches read data at the rising edge of RD.
	HWR	79	84	Output	High write: Indicates output of data on the upper data bus (D ₁₅ to D ₈) during external-device access.
	LWR	80	85	Output	Low write: Indicates output of data on the lower data bus (D ₇ to D ₀) during external-device access.
Interrupt signals	NMI	72	77	Input	Nonmaskable interrupt: Nonmaskable interrupt request signal.* The input edge can be selected in the NMI control register (NMICR).
	$\overline{\text{IRQ}}_0$	100	107	Input	Interrupt request 0 to 3: Maskable interrupt request signals. The type of input can be selected in the IRQ control register (IRQCR).
	$\overline{\text{IRQ}}_1$	101	108		
	$\overline{\text{IRQ}}_2$	108	115		
	$\overline{\text{IRQ}}_3$	109	116		

Note: * NMI is masked under certain conditions in on-board programming mode. For details, see section 16.4.9, “NMI Input Masking.”

	T3IOC ₂	9	10		
	T3OC ₁	67	72	Output	Output compare 1 and 2 (channel 3): Output compare pins for IPU channel 3.
	T3OC ₂	68	73		
	T4IOC ₁	11	12	Input/ Output	Input capture/output compare 1 and 2 (channel 4): Input capture or output compare pins for IPU channel 4.
	T4IOC ₂	12	13		
	T4OC ₁	62	67	Output	Output compare 1 and 2 (channel 4): Output compare pins for IPU channel 4.
	T4OC ₂	63	68		
	T5IOC ₁	13	14	Input/ Output	Input capture/output compare 1 and 2 (channel 5): Input capture or output compare pins for IPU channel 5.
	T5IOC ₂	14	15		
	T5OC ₁	64	69	Output	Output compare 1 and 2 (channel 5): Output compare pins for IPU channel 5.
	T5OC ₂	65	70		
	T6IOC ₁	15	16	Input/ Output	Input capture/output compare 1 and 2 (channel 6): Input capture or output compare pins for IPU channel 6.
	T6IOC ₂	16	17		
	T7IOC ₁	17	18	Input/ Output	Input capture/output compare 1 and 2 (channel 7): Input capture or output compare pins for IPU channel 7.
	T7IOC ₂	18	19		
	TCLK ₁	110	117	Input	Timer clock 1 to 3 (all channels): IPU external clock input pins. All channels can select these clock inputs.
	TCLK ₂	111	118		
	TCLK ₃	112	119		

Table 1-4 Pin Functions (cont)

Type	Symbol	Pin No.		I/O	Name and Function
		QFP-112	TFP-120		
A/D converter	AN ₁₁ –AN ₀	97–86	104–93	Input	Analog input 11 to 0: Analog input pins for the A/D converter.
	V _{REF}	85	92	Input	Reference power supply: Input pin for the A/D converter's full-scale reference voltage (2.7 V to 5.5 V).
	AV _{CC}	84	89	Input	Analog power supply: Power supply pin for analog circuits in the A/D converter. Connect to a regulated analog power supply separate from the other power supply pins.
	AV _{SS}	98	105	Input	Analog ground: Ground pin for analog circuits in the A/D converter. Connect to a regulated 0-V analog power supply separate from the other power supply pins.
	ADTRG	101	108	Input	A/D trigger: Trigger input for starting A/D conversion. Conversion is triggered by the falling edge of ADTRG.
Watchdog timer	RESO	19	20	Output	Reset output: If reset output is selected, a low pulse is output for 132 cycles when the watchdog timer overflows. RESO is an open-drain output pin and should be pulled up to V _{CC} externally, regardless of whether reset output is selected or not.
I/O ports	P1 ₇ –P1 ₀	43–36	46–39	Input/Output	Port 1: 8-bit input/output port. The direction of each bit can be selected in the port 1 data direction register (P1DDR).
	P2 ₇ –P2 ₀	34–27	37–32, 29, 28	Input/Output	Port 2: 8-bit input/output port. The direction of each bit can be selected in the port 2 data direction register (P2DDR).
	P3 ₅ –P3 ₀	25–20	26–21	Input/Output	Port 3: 6-bit input/output port. The direction of each bit can be selected in the port 3 data direction register (P3DDR). LEDs can be driven directly (10-mA sink).
	P4 ₇ –P4 ₀	18–11	19–12	Input/Output	Port 4: 8-bit input/output port with Schmitt-trigger inputs. The direction of each bit can be selected in the port 4 data direction register (P4DDR).

Table 1-4 Pin Functions (cont)

Type	Symbol	Pin No.		I/O	Name and Function
		QFP-112	TFP-120		
I/O ports	P5 ₇ –P5 ₀	9–2	10–3	Input/ Output	Port 5: 8-bit input/output port with Schmitt-trigger inputs. The direction of each bit can be selected in the port 5 data direction register (P5DDR). LEDs can be driven directly (10-mA sink).
	P6 ₄ –P6 ₀	112–108	119–115	Input/ Output	Port 6: 5-bit input/output port. The direction of each bit can be selected in the port 6 data direction register (P6DDR).
	P7 ₇ –P7 ₀	107–100	114–107	Input/ Output	Port 7: 8-bit input/output port. The direction of each bit can be selected in the port 7 data direction register (P7DDR).
	P8 ₃ –P8 ₀	97–94	104–101	Input	Port 8: 4-bit input port.
	P9 ₇ –P9 ₀	93–86	100–93	Input	Port 9: 8-bit input port.
	PA ₆ –PA ₀	68–62	73–67	Input/ Output	Port A: 8-bit input/output port. The direction of each bit can be selected in the port A data direction register (PADDDR).
	PB ₇ –PB ₀	61–54	66–62 59–57	Input/ Output	Port B: 8-bit input/output port with MOS input pull-up transistors. The direction of each bit can be selected in the port B data direction register (PBDDR).
	PC ₇ –PC ₀	52–45	55–48	Input/ Output	Port C: 8-bit input/output port with MOS input pull-up transistors. The direction of each bit can be selected in the port C data direction register (PCDDR).

Section 2 Operating Modes

2.1 Overview

2.1.1 Selection of Operating Mode

The H8/538F has seven operating modes (modes 1 to 7).

Modes 1 to 6 are externally expanded modes in which external memory and peripheral devices can be accessed. Modes 1, 2, and 6 are expanded minimum modes, supporting a 64-kbyte address space. Modes 3, 4, and 5 are expanded maximum modes, supporting a maximum 1-Mbyte address space.

Mode 7 is a single-chip mode: all ports are available for general-purpose input and output, but external addresses cannot be used.

Mode 0 is reserved for future use and must not be selected in the H8/538F.

Both the pin functions and address space vary depending on the mode. Table 2-1 summarizes the selection of operating modes.

Table 2-1 Operating Mode Selection

MCU Operating Mode	MD ₂	MD ₁	MD ₀	Description	CPU Operating Mode	On-Chip RAM	On-Chip ROM	Data Bus Width
Mode 0	0	0	0	—	—	—	—	—
Mode 1	0	0	1	Expanded minimum mode	Minimum mode	Enabled*1	Disabled	16 bits
Mode 2*3	0	1	0	Expanded minimum mode	Minimum mode	Enabled*1	Enabled	8 bits
Mode 3	0	1	1	Expanded maximum mode	Maximum mode	Enabled*1	Disabled	16 bits
Mode 4*3	1	0	0	Expanded maximum mode	Maximum mode	Enabled*1	Enabled	16 bits
Mode 5	1	0	1	Expanded maximum mode	Maximum mode	Enabled*1	Disabled	16 bits*2

Table 2-1 Operating Mode Selection (cont)

MCU Operating Mode	MD ₂	MD ₁	MD ₀	Description	CPU Operating Mode	On-Chip RAM	On-Chip ROM	Data Bus Width
Mode 6	1	1	0	Expanded minimum mode	Minimum mode	Enabled* ¹	Disabled	16 bits* ²
Mode 7* ³	1	1	1	Single-chip mode	Minimum mode	Enabled	Enabled	—

Legend

- 0: Low
1: High
—: Not available

Notes: 1. If the RAM enable bit (RAME) in the RAM control register (RAMCR) is cleared to 0, these addresses become external addresses.
2. Eight-bit three-state-access address space after a reset.
3. If the mode pins are programmed for mode 2, 4, or 7 and 12 V is applied to the V_{PP} pin, the flash memory can be written to or erased. For details see section 16, “Flash Memory.”

2.1.2 Register Configuration

The MCU operating mode can be monitored in the mode control register (MDCR). Table 2-2 summarizes this register.

Table 2-2 Register Configuration

Address	Name	Abbreviation	R/W	Initial Value
H'FF19	Mode control register	MDCR	R	Undetermined

2.2 Mode Control Register

The mode control register (MDCR) is an eight-bit register that indicates the current operating mode of the H8/538F. The MDCR bit structure is shown next.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	MDS2	MDS1	MDS0
Initial value	1	1	0	0	0	—*	—*	—*
R/W	—	—	—	—	—	R	R	R

— Reserved bits

— Mode select 2 to 0
Bits indicating the current operating mode

Note: * Determined by pins MD₂ to MD₀. MDCR latches the inputs at the mode pins (MD₂ to MD₀) at the rise of the $\overline{\text{RES}}$ signal.

(1) **Bits 7 and 6—Reserved:** Read-only bits, always read as 1.

(2) **Bits 5 to 3—Reserved:** Read-only bits, always read as 0.

(3) **Bits 2 to 0—Mode Select 2 to 0 (MDS2 to MDS0):** These bits indicate the values of pins MD₂ to MD₀ latched at the rise of the $\overline{\text{RES}}$ signal (the current operating mode).

MDS2 to MDS0 correspond to MD₂ to MD₀.

MDS2 to MDS0 are read-only bits.

2.3 Operating Mode Descriptions

2.3.1 Mode 1 (Expanded Minimum Mode)

In mode 1 the data bus is 16 bits wide. The bus controller's byte area register (ARBT) is enabled in mode 1, so part of the address space can be accessed with an eight-bit bus width. The maximum address space supported in mode 1 is 64 kbytes.

The on-chip ROM is disabled in mode 1.

2.3.2 Mode 2 (Expanded Minimum Mode)

In mode 2 the data bus is eight bits wide. The on-chip ROM is enabled.

The maximum address space supported in mode 2 is 64 kbytes.

The bus controller's byte-area register (ARBT) is disabled in mode 2.

2.3.3 Mode 3 (Expanded Maximum Mode)

In mode 3 the data bus is 16 bits wide. The bus controller's byte area register (ARBT) is enabled in mode 3, so part of the address space can be accessed with an eight-bit bus width. The maximum address space supported in mode 3 is 1 Mbyte.

The on-chip ROM is disabled in mode 3.

2.3.4 Mode 4 (Expanded Maximum Mode)

In mode 4 the data bus is 16 bits wide. The bus controller's byte area register (ARBT) is enabled in mode 4, so part of the address space can be accessed with an eight-bit bus width. The maximum address space supported in mode 4 is 1 Mbyte. The on-chip ROM is enabled.

2.3.5 Modes 5 and 6

Mode 5 is functionally identical to mode 3, and mode 6 is functionally identical to mode 1. When the chip comes out of reset, however, the bus controller's byte area register (ARBT) is disabled in modes 5 and 6 and eight-bit, three-state access is performed throughout the address space. The byte area register can be enabled by setting the BCRE bit to 1 in the bus control register (BCR).

2.3.6 Mode 7 (Single-Chip Mode)

The external address space cannot be accessed.

2.4 Pin Functions in Each Operating Mode

The pin functions of the I/O ports vary depending on the operating mode.

Table 2-3 summarizes the functions in each mode.

Selection of pin functions is described in section 9, “I/O Ports.”

Table 2-3 Pin Functions in Each Mode

Port	Expanded Minimum Modes		Expanded Maximum Modes		Single-Chip Mode
	Modes 1 and 6	Mode 2	Modes 3 and 5	Mode 4	Mode 7
Port 1	Data bus (D ₁₅ to D ₈)	Data bus (D ₁₅ to D ₈)	Data bus (D ₁₅ to D ₈)	Data bus (D ₁₅ to D ₈)	Input/output port
Port 2	Data bus (D ₇ to D ₀)	Input/output port	Data bus (D ₇ to D ₀)	Data bus (D ₇ to D ₀)	Input/output port

Port 8	Input port* ³	Input port* ³	Input port* ³	Input port* ³	Input port* ³
Port 9	Input port* ³	Input port* ³	Input port* ³	Input port* ³	Input port* ³
Port A	Input/output port* ¹ $\overline{\text{BREQ}}$, $\overline{\text{BACK}}$, $\overline{\text{WAIT}}$	Input/output port* ¹ $\overline{\text{BREQ}}$, $\overline{\text{BACK}}$, $\overline{\text{WAIT}}$	Input/output port $\overline{\text{BREQ}}$, $\overline{\text{BACK}}$, $\overline{\text{WAIT}}$, address bus (A ₁₉ to A ₁₆)	Input/output port $\overline{\text{BREQ}}$, $\overline{\text{BACK}}$, $\overline{\text{WAIT}}$, address bus (A ₁₉ to A ₁₆)	Input/output port* ¹
Port B	Address bus (A ₁₅ to A ₈)	Input port/ address bus (A ₁₅ to A ₈)	Address bus (A ₁₅ to A ₈)	Input port/ address bus (A ₁₅ to A ₈)	Input/output port
Port C	Address bus (A ₇ to A ₀)	Input port/ address bus (A ₇ to A ₀)	Address bus (A ₇ to A ₀)	Input port/ address bus (A ₇ to A ₀)	Input/output port

Notes: 1. Also used for timer output.
2. Also used for serial communication.
3. Also used for A/D conversion.

2.5 Memory Map in Each Mode

Figure 2-1 shows a memory map for the expanded minimum modes (modes 1, 2, and 6). Figure 2-2 shows a memory map for the expanded maximum modes (modes 3, 4, and 5). Figure 2-3 shows a memory map for the single-chip mode (mode 7).

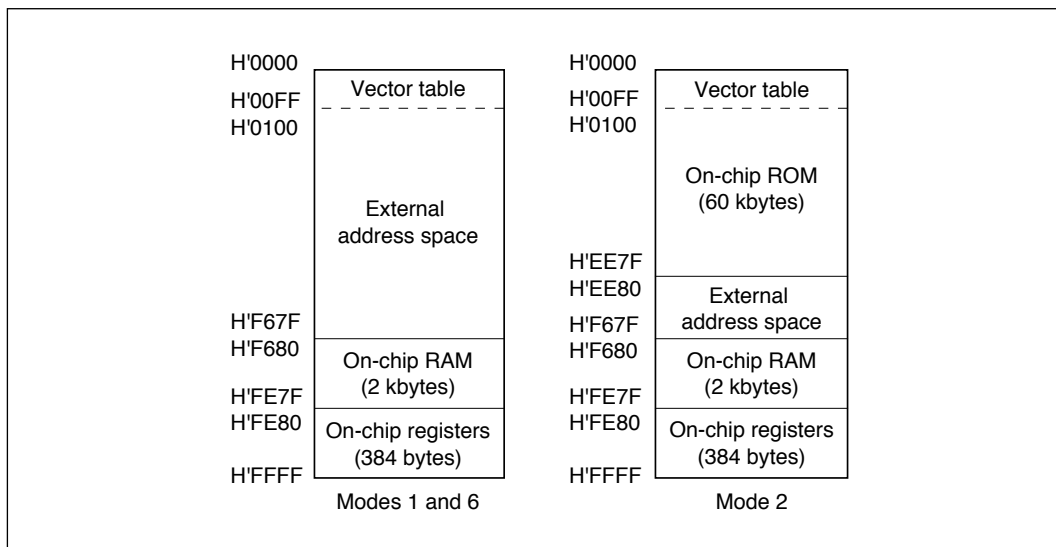

Figure 2-1 Memory Map in Expanded Minimum Modes

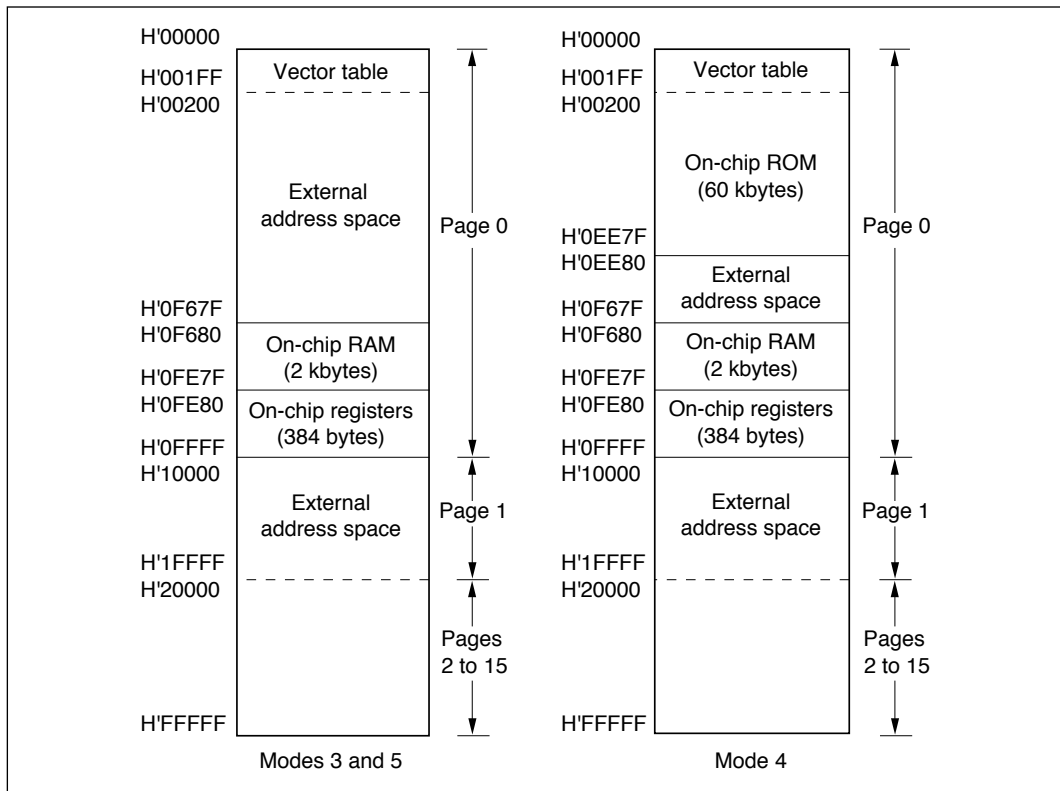

Figure 2-2 Memory Map in Expanded Maximum Modes

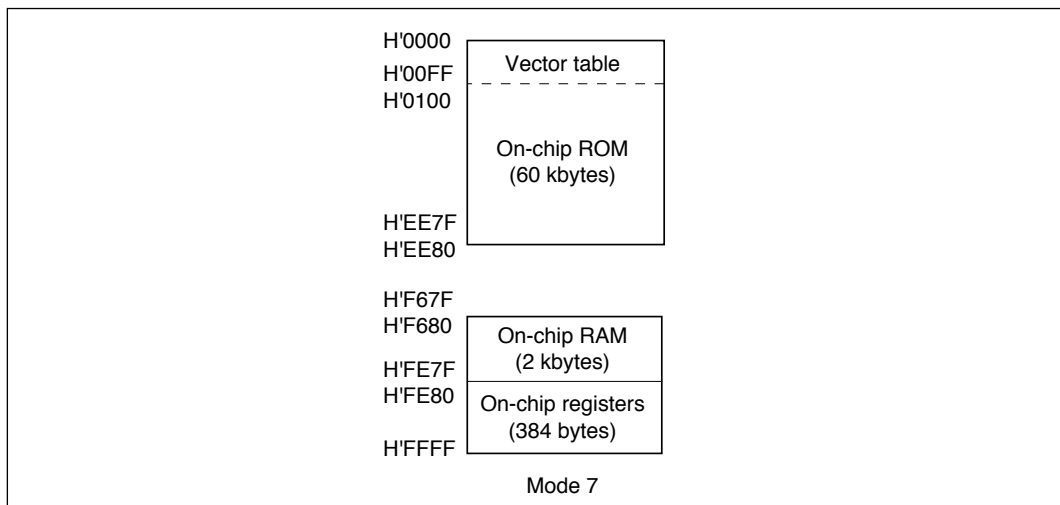

Figure 2-3 Memory Map in Single-Chip Mode

Section 3 CPU

3.1 Overview

The H8/538F has the H8/500 CPU, which is common to all chips in the H8/500 Family. The H8/500 CPU is a high-speed central processing unit that is designed for realtime control and supports a large address space. Its architecture features eight general registers, 16-bit internal data paths, and an optimized instruction set.

The H8/500 CPU is suitable for control of a wide range of medium-scale office and industrial equipment.

Section 3 summarizes the CPU architecture, instruction set, and operation.

3.1.1 Features

The main features of the H8/500 CPU are listed below.

- General-register machine
 - Eight 16-bit general registers
 - Seven control registers (two 16-bit registers, five 8-bit registers)
- High-speed operation: 16 MHz maximum clock rate

At 16 MHz a register-register add operation takes only 125 ns.
- Maximum address space: 1 Mbyte*
 - Managed in 64-kbyte pages
 - Four pages available simultaneously: code page, stack page, data page, and extended page.

Note: * The CPU architecture supports up to 16 Mbytes, but the H8/538F chip has only enough pins to address 1 Mbyte.
- Two CPU operating modes
 - Minimum mode: 64-kbyte address space
 - Maximum mode: 1-Mbyte address space
- Highly orthogonal instruction set

Addressing modes and data sizes can be specified independently within each instruction.

- Register and memory addressing modes

Register-register and register-memory (or memory-register) operations are supported.

- Instruction set optimized for C language

In addition to the general registers and orthogonal instruction set, the CPU has special short formats for frequently-used instructions and addressing modes.

3.1.2 Address Space

The H8/500 CPU has different address spaces in its two operating modes, the minimum mode and maximum mode. The CPU operating mode is selected by the input at the mode pins (MD₂ to MD₀) at a reset. Table 3-1 summarizes the CPU operating modes. Figure 3-1 shows a memory map for the minimum mode. Figure 3-2 shows a memory map for the maximum mode.

Table 3-1 CPU Operating Modes

Operating Mode	Features
Minimum mode	Maximum combined size of program area and data area: 64 kbytes
Maximum mode	Maximum combined size of program area and data area: 1 Mbyte

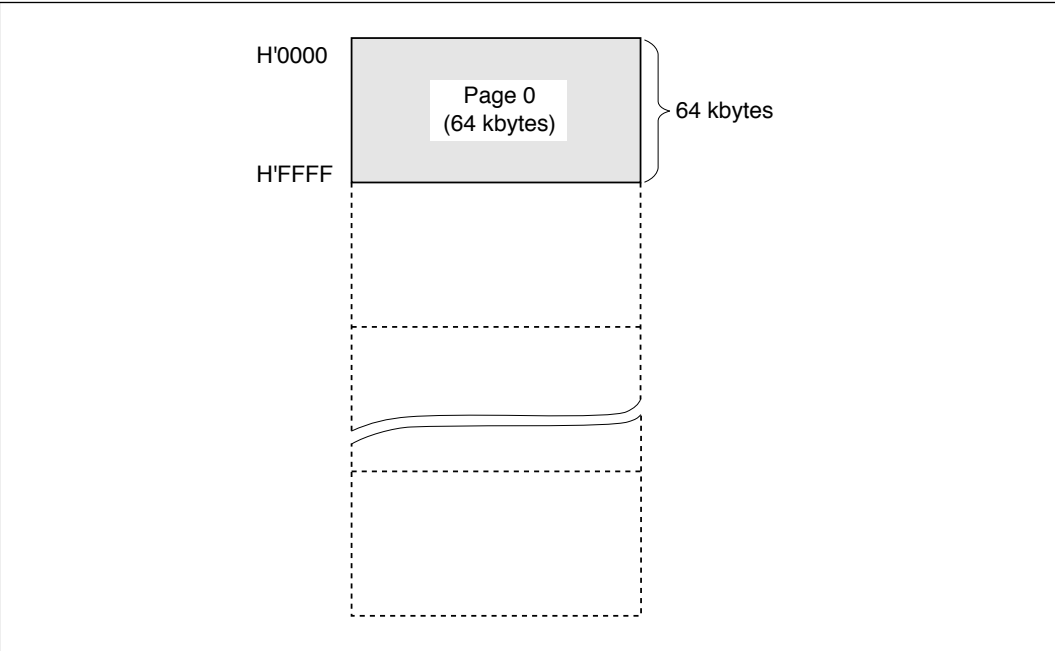

Figure 3-1 Memory Map in Minimum Mode

Figure 3-2 Memory Map in Maximum Mode

3.1.3 Programming Model

Figure 3-3 shows a programming model of the H8/500 CPU.

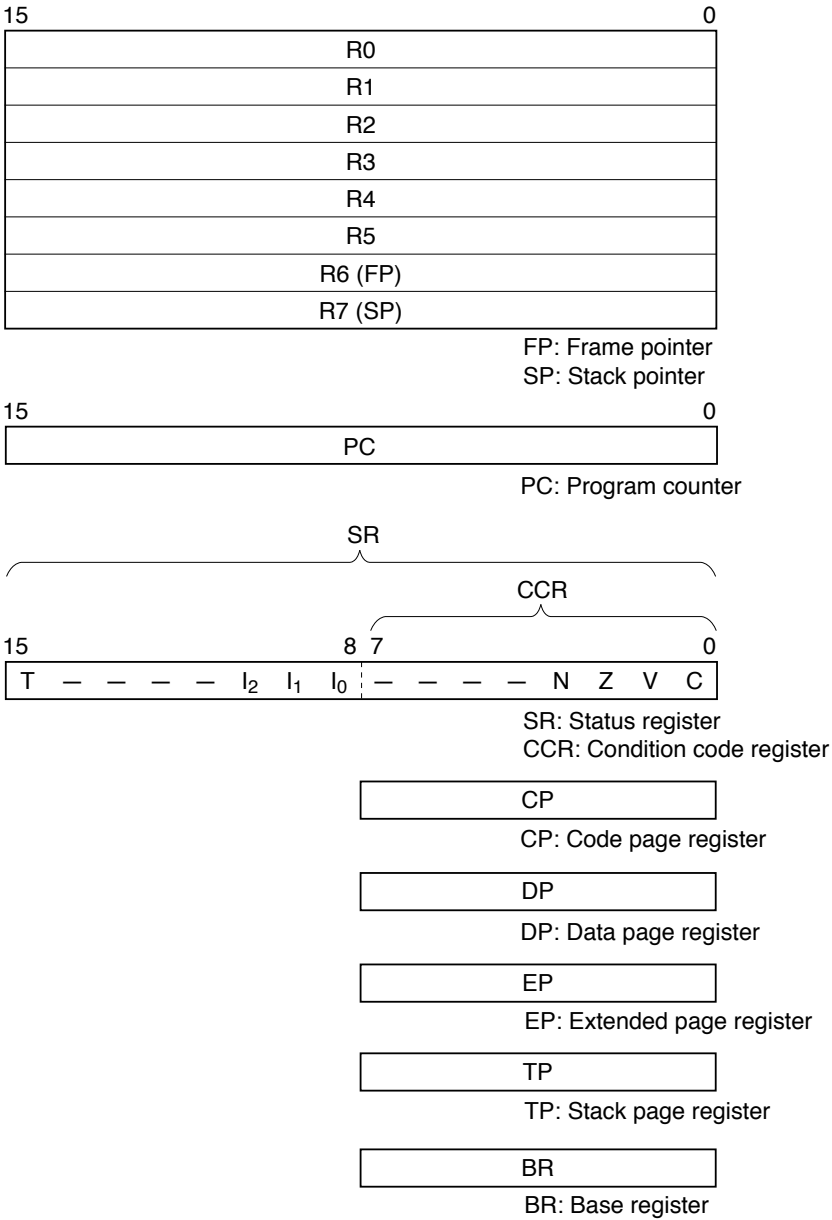

Figure 3-3 Programming Model

3.2 General Registers

The H8/500 CPU has eight 16-bit general registers.

The general registers are described next.

3.2.1 Overview

All eight of the general registers are functionally alike; there is no distinction between data registers and address registers. When these registers are accessed as data registers, either byte or word size can be selected.

When these registers are accessed as address registers, word size is implicitly assumed.

3.2.2 Register Configuration

Figure 3-4 shows the general register configuration.

Figure 3-4 General Register Configuration

3.2.3 Stack Pointer

R7 functions as the stack pointer (SP), and is used implicitly in exception handling and subroutine calls. It is also used implicitly in pre-decrement or post-increment mode by the LDM and STM instructions, which load and store multiple registers on the stack.

3.2.4 Frame Pointer

R6 functions as a frame pointer (FP). The LINK and UNLK instructions use R6 implicitly to reserve or release a stack frame.

3.3 Control Registers

The H8/500 CPU has two control registers.

The control registers are described next.

3.3.1 Overview

The control registers include a 16-bit program counter and a 16-bit status register.

The program counter and status register are described next.

3.3.2 Register Configuration

Figure 3-5 illustrates the program counter and status register.

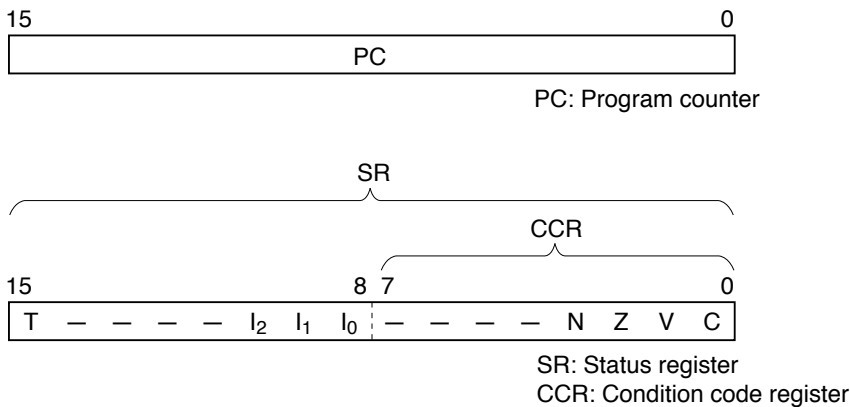

Figure 3-5 Program Counter and Status Register

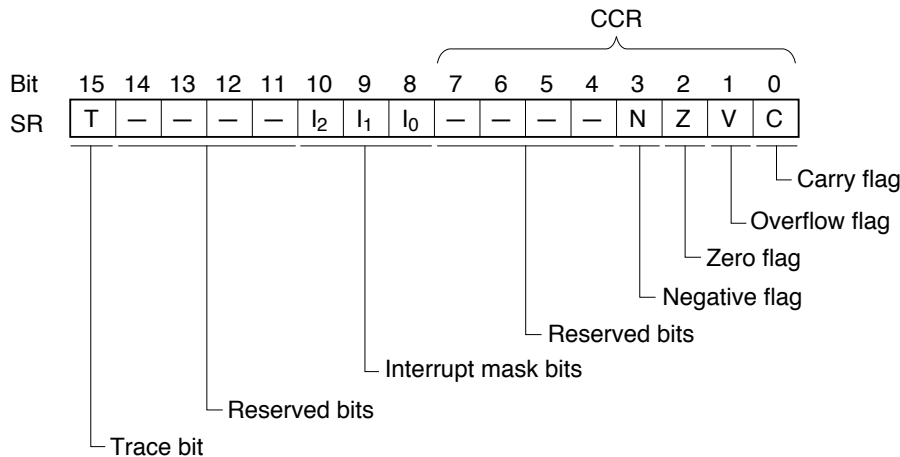

3.3.3 Program Counter

The 16-bit program counter (PC) indicates the address of the next instruction the CPU will execute.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PC																

3.3.4 Status Register

The 16-bit status register (SR) contains status flags that indicate the internal state of the CPU.

The lower eight bits of the status register are referred to as the condition code register (CCR). Byte access to the CCR is possible.

(1) **Bit 15—Trace (T):** Selects trace mode.

Bit 15

T	Description
0	Instructions are executed in succession (initial mode after reset)
1	Trace exception handling starts after each instruction (trace mode)

For information about trace exception handling, see section 4.4, “Trace.”

(2) **Bits 14 to 11—Reserved:** Read-only bits, always read as 0.

(3) **Bits 10 to 8—Interrupt mask (I₂, I₁, I₀):** These bits indicate the interrupt request mask level (0 to 7) of the program that is currently executing. Table 3-2 explains the interrupt request mask levels.

Table 3-2 Interrupt Mask Levels

Interrupt Mask			Level	Priority	Acceptable Interrupts
I ₂	I ₁	I ₀			
1	1	1	7	<div> <div>High</div> <div>↑</div> <div>↓</div> <div>Low</div> </div>	NMI
1	1	0	6		Level 7 and NMI
1	0	1	5		Levels 6 to 7 and NMI
1	0	0	4		Levels 5 to 7 and NMI
0	1	1	3		Levels 4 to 7 and NMI
0	1	0	2		Levels 3 to 7 and NMI
0	0	1	1		Levels 2 to 7 and NMI
0	0	0	0		Levels 1 to 7 and NMI

The CPU accepts only interrupts higher than the interrupt mask level. NMI (level 8) is accepted at any interrupt mask level. After accepting an interrupt, the H8/500 CPU updates I₂, I₁, and I₀ to the level of the interrupt. Table 3-3 indicates the values of the interrupt mask bits after an interrupt is accepted. A reset sets all three interrupt mask bits to 1.

Table 3-3 Interrupt Mask Bits (I₂, I₁, I₀) after an Interrupt is Accepted

Level of Interrupt Accepted	Interrupt Mask		
	I ₂	I ₁	I ₀
NMI (8)	1	1	1
7	1	1	1
6	1	1	0
5	1	0	1
4	1	0	0
3	0	1	1
2	0	1	0
1	0	0	1

(4) **Bits 7 to 4—Reserved:** Read-only bits, always read as 0.

(5) **Bit 3—Negative (N):** The most significant data bit, regarded as a sign bit.

(6) **Bit 2—Zero (Z):** Set to 1 to indicate zero data and cleared to 0 at other times.

(7) **Bit 1—Overflow (V):** Set to 1 when an arithmetic overflow occurs and cleared to 0 at other times.

(8) **Bit 0—Carry (C):** Set to 1 when a carry or borrow occurs at the most significant data bit and cleared to 0 at other times.

The specific changes that occur in the condition code bits when each instruction is executed are listed in Appendix A.1 “Instruction Tables.” See the *H8/500 Series Programming Manual* for further details.

3.4 Page Registers

The H8/500 CPU has four page registers.

The page registers are described next.

3.4.1 Overview

All page registers are eight-bit registers.

The four page registers are the code page register (CP), data page register (DP), extended page register (EP), and stack page register (SP).

The page registers are not used in minimum mode. In maximum mode, the page registers combine with the program counter and general registers to generate 24-bit effective addresses as shown in figure 3-6, thereby expanding the program area, data area, and stack area.

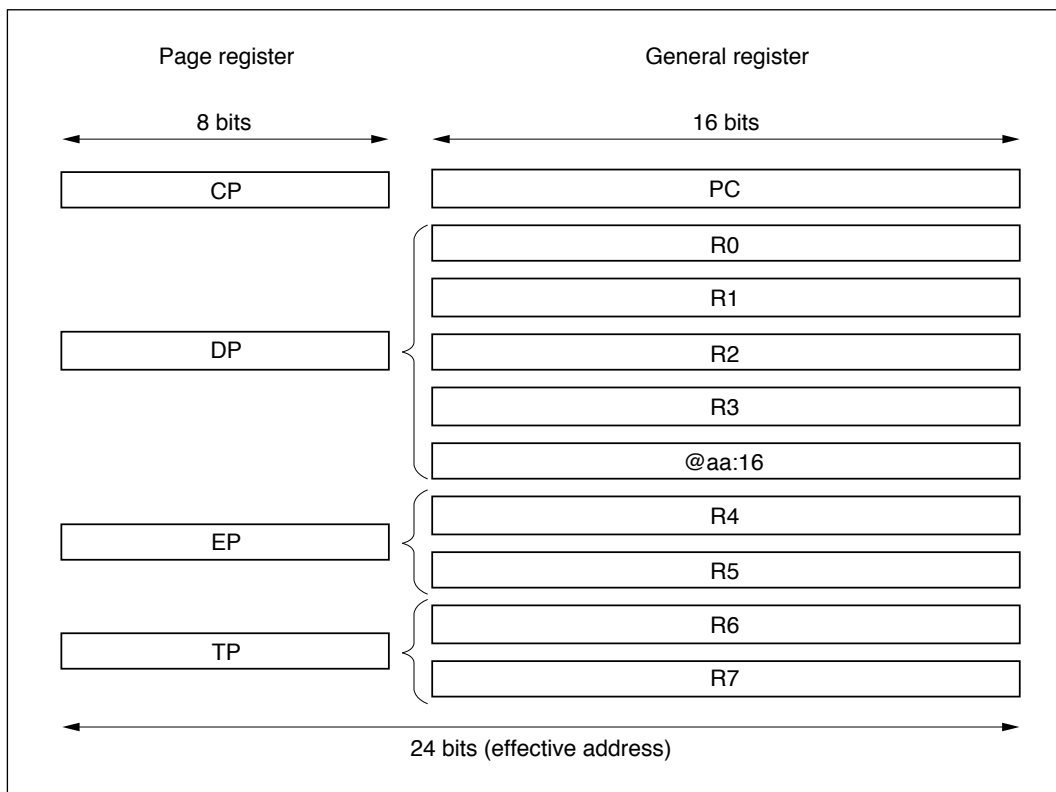

Figure 3-6 Combinations of Page Registers with PC and General Registers

3.4.2 Register Configuration

Figure 3-7 shows the page registers.

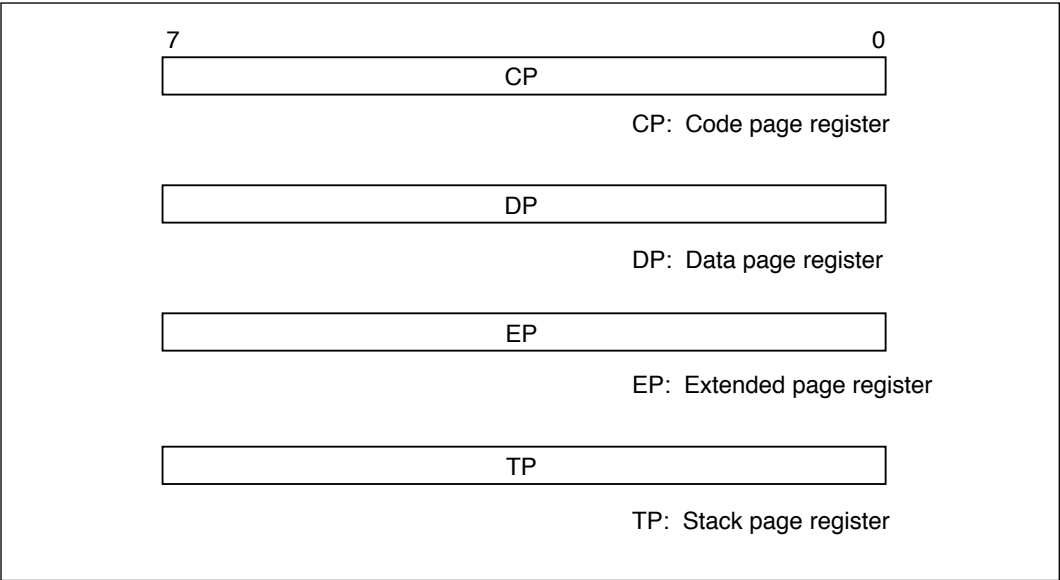

Figure 3-7 Page Registers

3.4.3 Code Page Register

The code page register (CP) combines with the program counter to generate a 24-bit program code address. CP contains the upper eight bits of the address.

Bit	7	6	5	4	3	2	1	0
CP								

In maximum mode, CP is initialized at a reset to a value loaded from the vector table, and CP and PC are both saved and restored in exception handling.

The LDC instruction can be used to modify the CP contents.

3.4.4 Data Page Register

The data page register (DP) combines with general registers R0 to R3 to generate a 24-bit effective address. DP contains the upper eight bits of the address.

Bit	7	6	5	4	3	2	1	0
DP								

DP is used to calculate effective addresses in register indirect addressing mode using R0 to R3, and in absolute addressing mode (but not short absolute addressing mode).

The LDC instruction can be used to modify the DP contents.

3.4.5 Extended Page Register

The extended page register (EP) combines with general register R4 or R5 to generate a 24-bit operand address. EP contains the upper eight bits of the address.

Bit	7	6	5	4	3	2	1	0
EP								

EP is used to calculate effective addresses in register indirect addressing mode using R4 or R5.

The LDC instruction can be used to modify the EP contents.

3.4.6 Stack Page Register

The stack page register (TP) combines with R6 (SP) or R7 (FP) to generate a 24-bit stack address. TP contains the upper eight bits of the address.

Bit	7	6	5	4	3	2	1	0
TP								

TP is used to calculate effective addresses in the register indirect addressing mode using R6 or R7, in exception handling, and in subroutine calls.

The LDC instruction can be used to modify the TP contents.

3.5 Base Register

The H8/500 CPU has one 8-bit base register.

The base register is described next.

3.5.1 Overview

The eight-bit base register (BR) stores the base address used in short absolute addressing mode (representing the upper eight bits of an address in page 0). Figure 3-8 illustrates the base register and short absolute addressing mode. In this addressing mode a 16-bit effective address is generated by using the BR contents as the upper eight bits and an address given in the instruction code as the lower eight bits. The short absolute addressing mode always addresses page 0.

The LDC instruction can be used to modify the BR contents.

Figure 3-8 Short Absolute Addressing Mode and Base Register

3.5.2 Register Configuration

Figure 3-9 shows the base register.

Figure 3-9 Base Register

3.6 Data Formats

The H8/500 CPU can process five types of data: one-bit data, four-bit BCD data, eight-bit (byte) data, 16-bit (word) data, and 32-bit (longword) data. Bit manipulation instructions operate on one-bit data. Decimal arithmetic instructions operate on four-bit BCD data. All instructions except certain arithmetic and data transfer instructions can operate on byte and word data. Multiply and divide instructions operate on longword data.

The data formats are described next.

3.6.1 Data Formats in General Registers

Table 3-4 indicates the data formats in general registers. All sizes of data can be stored: one-bit data, four-bit BCD data, eight-bit (byte) data, 16-bit (word) data, and 32-bit (longword) data.

In addressing of one-bit data, bit 15 is the most significant bit and bit 0 is the least significant bit. BCD and byte data are stored in the lower eight bits of a general register. All 16 bits of a general register are used to store word data. Two general registers are used for longword data: the upper 16 bits are stored in R_n (n must be an even number); the lower 16 bits are stored in R_{n+1} .

Operations performed on BCD data or byte data do not alter the upper eight bits of the register.

Table 3-4 General Register Data Formats

Data Type	Register No.	Data Structure
One bit	R_n	<div>150</div> <div>1514131211109876543210</div>
BCD	R_n	<div>7430</div> <div>Don't careUpper digitLower digit</div>
Byte	R_n	<div>70</div> <div>Don't careMSBLSB</div>
Word	R_n	<div>150</div> <div>MSBLSB</div>
Longword*	R_n R_{n+1}	<div>3116</div> <div>MSBUpper 16 bits</div> <div>Lower 16 bitsLSB</div> <div>150</div>

Note: * For longword data n must be even (0, 2, 4, or 6).

3.6.2 Data Formats in Memory

Table 3-5 indicates the data formats in memory.

Instructions that access bit data in memory have byte or word operands. The instruction specifies a bit number to indicate a specific bit in the operand.

Access to word data in memory must always begin at an even address. Access to word data starting at an odd address causes an address error. The upper eight bits of word data are stored in address n (where n is an even number); the lower eight bits are stored in address $n + 1$.

Table 3-5 Data Formats in Memory

Data Type	Data Format									
One bit (in byte operand data)	Address n	<table><tr><td>7</td><td>6</td><td>5</td><td>4</td><td>3</td><td>2</td><td>1</td><td>0</td></tr></table>	7	6	5	4	3	2	1	0
7	6	5	4	3	2	1	0			
One bit (in word operand data)	Even address	<table><tr><td>15</td><td>14</td><td>13</td><td>12</td><td>11</td><td>10</td><td>9</td><td>8</td></tr></table>	15	14	13	12	11	10	9	8
15	14	13	12	11	10	9	8			
	Odd address	<table><tr><td>7</td><td>6</td><td>5</td><td>4</td><td>3</td><td>2</td><td>1</td><td>0</td></tr></table>	7	6	5	4	3	2	1	0
7	6	5	4	3	2	1	0			
Byte	Address n	<table><tr><td>MSB</td><td>LSB</td></tr></table>	MSB	LSB

Lower 8 bits	LSB									

3.6.3 Stack Data Formats

Table 3-6 shows the data formats on the stack.

When the stack is accessed in exception processing (to save or restore the program counter, code page register, or status register), word access is always performed, regardless of the actual data size. Similarly, when the stack is accessed by an instruction using the pre-decrement or post-increment register indirect addressing mode specifying $R7$ ($@-R7$ or $@R7+$), which is the stack pointer, word access is performed regardless of the operand size specified in the instruction. Programs should be coded so that the stack pointer always indicates an even address. An address error will occur if the stack pointer indicates an odd address.

Table 3-6 Data Formats on the Stack

Data Type	Data Format	
Byte data on stack	Even address	Undetermined data
	Odd address	MSBLSB
Word data on stack	Even address	MSBUpper 8 bits
	Odd address	Lower 8 bitsLSB

3.7 Addressing Modes and Effective Address Calculation

The H8/500 CPU supports seven addressing modes.

These modes and the corresponding effective address calculations are described next.

3.7.1 Addressing Modes

The seven addressing modes supported by the H8/500 CPU are:

- 1. Register direct
- 2. Register indirect
- 3. Register indirect with displacement
- 4. Register indirect with pre-decrement or post-increment
- 5. Immediate
- 6. Absolute
- 7. PC-relative

Due to the highly orthogonal nature of the instruction set, most instructions having operands can use any applicable addressing mode from 1 through 6. The PC-relative mode 7 is used by branching instructions.

In most instructions, the addressing mode is specified in the effective address (EA) field and effective address extension (if present).

Table 3-7 indicates how the addressing mode is specified in the effective address field.

(1) Register Direct Addressing Mode: The contents of a general register Rn are used directly as operand data. This addressing mode is specified by giving the general register name.

Register direct addressing mode

(2) Register Indirect Addressing Mode: The contents of a general register Rn are used as a memory address, and data access is performed at that memory address. This addressing mode is specified by giving the general register name with an address qualifier (@).

Register indirect addressing mode

(3) Register Indirect Addressing Mode with Displacement: A displacement value is added to the contents of a general register Rn, the sum is used as a memory address, and data access is performed at that memory address. This addressing mode is specified by giving the general register name with the address qualifier (@) and an 8-bit or 16-bit displacement value.

Register indirect addressing mode with displacement

(4) Register Indirect Addressing Mode with Pre-Decrement or Post-Increment: In register indirect addressing mode with pre-decrement, a general register value is first decremented by -1 or -2 , then the result is used as a memory address and data access is performed at that memory address. In register indirect addressing mode with post-increment, a general register value is used as a memory address and data access is performed at that memory address, then the register value is incremented by 1 or 2. This addressing mode is specified by giving the general register name with the address qualifier (@) and a plus or minus sign (+ or $-$).

Register indirect addressing mode with pre-decrement or post-increment

(5) Immediate Addressing Mode: Eight-bit or 16-bit immediate data given in the instruction are used directly as the operand data. This addressing mode is specified by giving the immediate data with a data qualifier (#).

Immediate addressing mode

(6) Absolute Addressing Mode: Data access is performed at a memory address given as a 16-bit absolute address in the instruction, or given as an eight-bit absolute address in the instruction and combined with the base register (BR) value. This addressing mode is specified by giving the absolute address with an address qualifier.

Absolute addressing mode

(7) PC-Relative Addressing Mode: An eight-bit or 16-bit displacement value given in the instruction is added to the program counter value, the sum is used as a memory address, and this memory address is moved into the program counter. This addressing mode is specified by giving the displacement value.

PC-relative addressing mode

Table 3-7 Addressing Modes

No.	Addressing Mode	Mnemonic	EA Field	EA Extension																	
1	Register direct	Rn	<table><tr><td>1</td><td>0</td><td>1</td><td>0</td><td>Sz</td><td>r</td><td>r</td><td>r</td></tr><tr><td colspan="5"></td><td>*1</td><td colspan="3">*2</td></tr></table>	1	0	1	0	Sz	r	r	r						*1	*2			None

3.8 Operating Modes

The H8/500 CPU has two operating modes: minimum mode and maximum mode. The mode is selected by the mode pins (MD_2 to MD_0).

The operating modes are described next.

3.8.1 Minimum Mode

Minimum mode supports an address space of up to 64 kbytes. The page registers are ignored. Instructions that branch across page boundaries (PJMP, PJSR, PRTS, PRTD) are invalid.

3.8.2 Maximum Mode

In maximum mode the page registers are valid, expanding the maximum address space to 1 Mbyte. It is possible to move from one page to another with branching instructions (PJMP, PJSR, PRTS, PRTD) and when branching to interrupt-handling routines.

When data access crosses a page boundary, the program must rewrite the page register before it can access the data in the next page.

For further information on the operating modes, see section 2, “Operating Modes.”

3.9 Basic Operational Timing

When an external clock signal is fed to the XTAL pin or a crystal resonator is connected across the XTAL and EXTAL pins, the on-chip clock oscillator circuit corrects the duty cycle of the applied signal to create the system clock (ϕ). Figure 3-10 shows a block diagram of the clock oscillator.

The basic operational timing of the H8/500 CPU is described next.

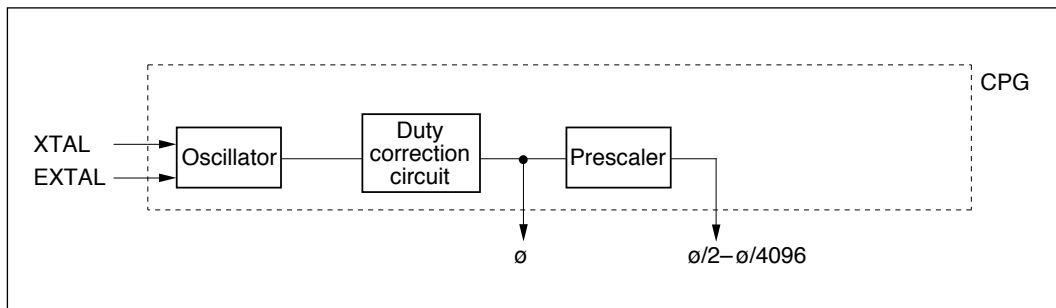

Figure 3-10 Block Diagram of Clock Oscillator

3.9.1 Overview

The system clock (ϕ) created by correcting the duty cycle of the oscillator clock (f_{OSC}) is the H8/500 CPU's time base. One cycle of the system clock is referred to as a "state." The H8/500 CPU's bus cycle consists of two or three states. The CPU uses different methods to access on-chip memory, the on-chip register field, and external devices.

These access methods are described next.

3.9.2 Access to On-Chip Memory

On-chip memory is accessed in two states using a 16-bit bus. Figure 3-11 shows the on-chip memory access cycle. Figure 3-12 shows the pin states during on-chip memory access.

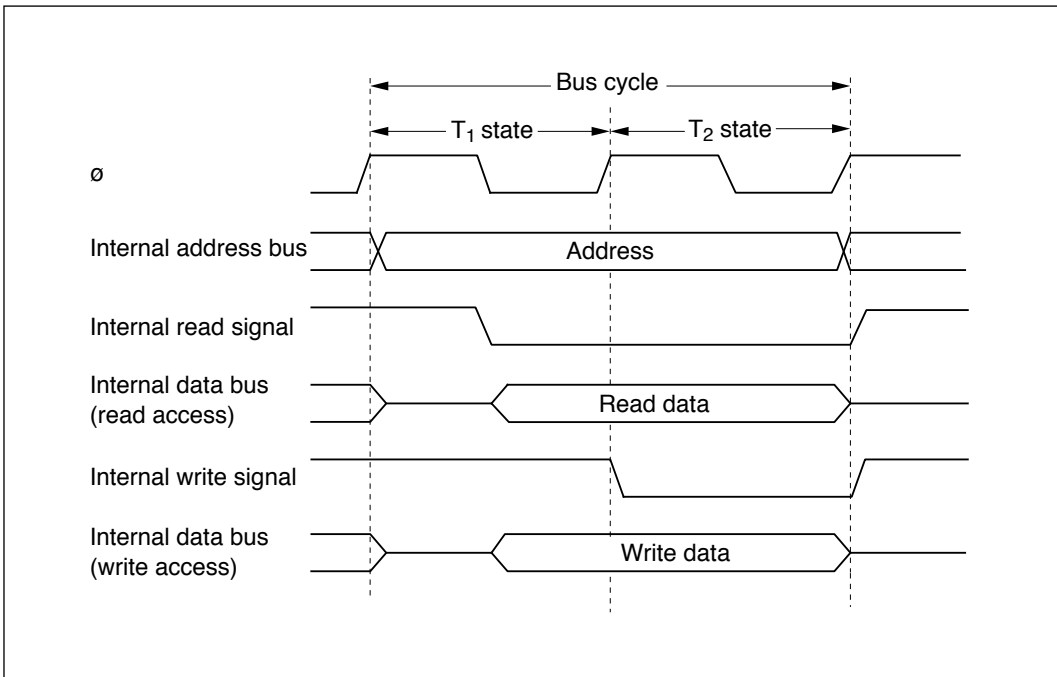

Figure 3-11 On-Chip Memory Access Cycle

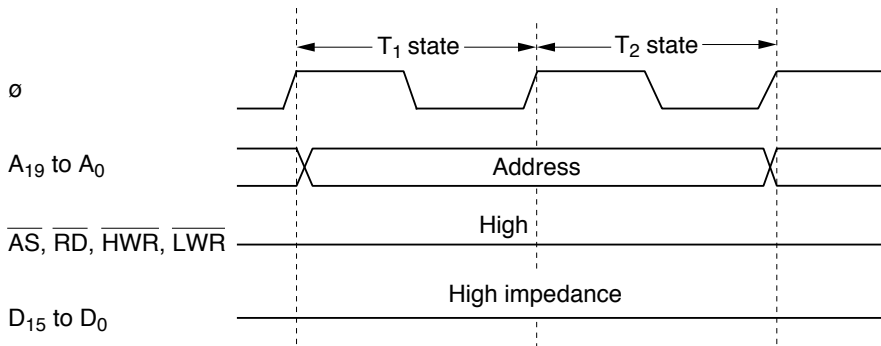

Figure 3-12 Pin States during Access to On-Chip Memory

3.9.3 Access to Two-State-Access Address Space

Two-state access permits high-speed processing. No wait states can be inserted in access to the two-state-access address space. The external two-state-access address space is accessed via a 16-bit bus. Figure 3-13 shows the access cycle for the external two-state-access address space.

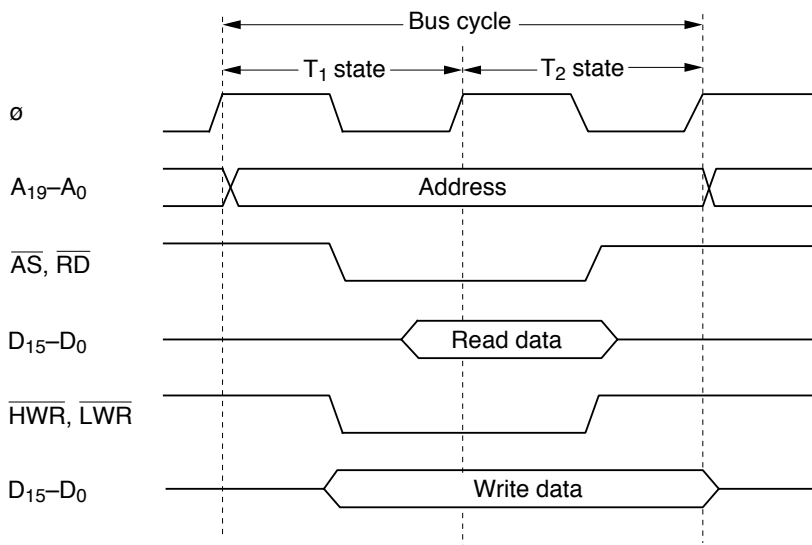

Figure 3-13 Access Cycle for External Two-State-Access Address Space

3.9.4 Access to On-Chip Supporting Modules

The on-chip supporting modules are always accessed in three states. The data bus is eight bits wide, except that some of the registers in the 16-bit integrated-timer pulse unit (IPU) are accessed via a 16-bit data bus.

Figure 3-14 shows the on-chip supporting module access cycle. Figure 3-15 indicates the pin states during access to an on-chip supporting module.

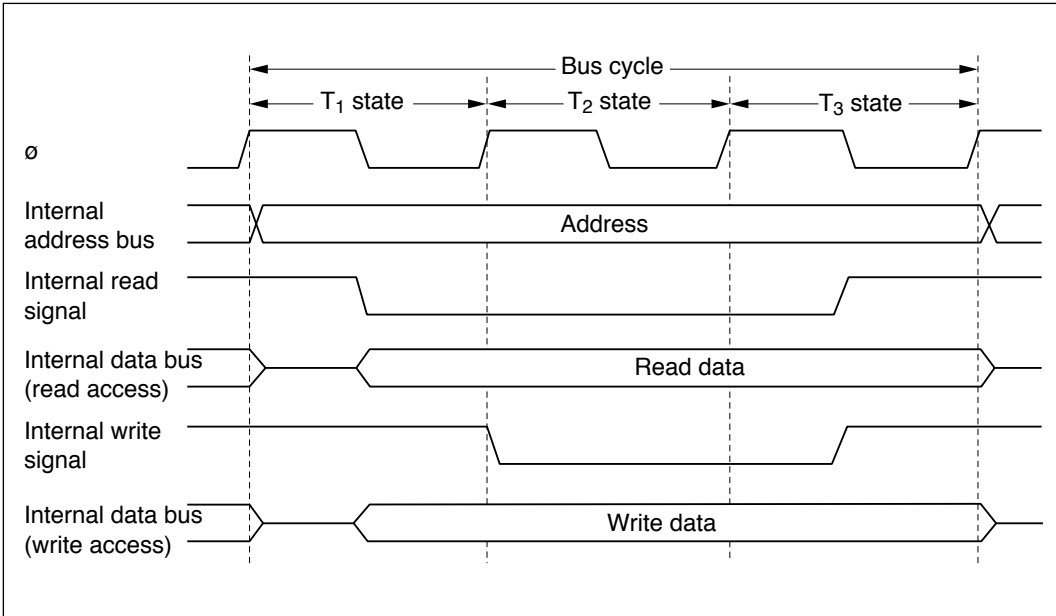

Figure 3-14 Access Cycle for On-Chip Supporting Modules

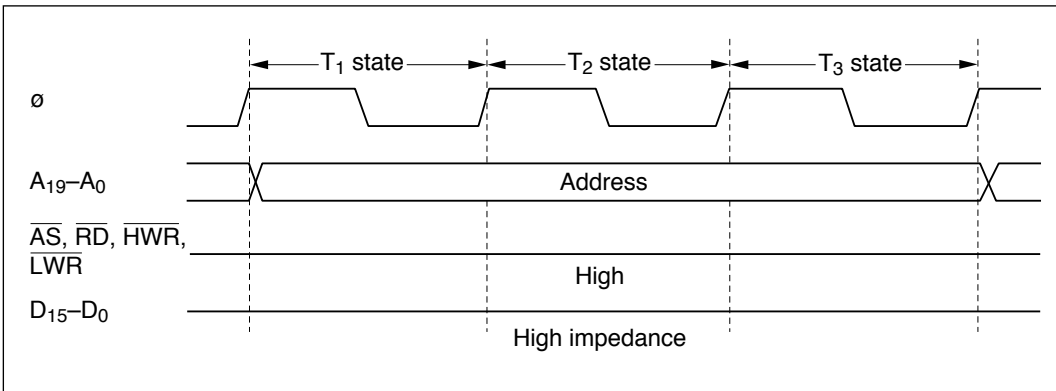

Figure 3-15 Pin States during Access to On-Chip Supporting Modules

3.9.5 Access to Three-State-Access Address Space

Three-state access is used for interfacing to low-speed devices.

The wait-state controller (WSC) can insert wait states (T_W) in access to the three-state-access address space.

Figure 3-16 shows the three-state read access cycle. Figure 3-17 shows the three-state write access cycle.

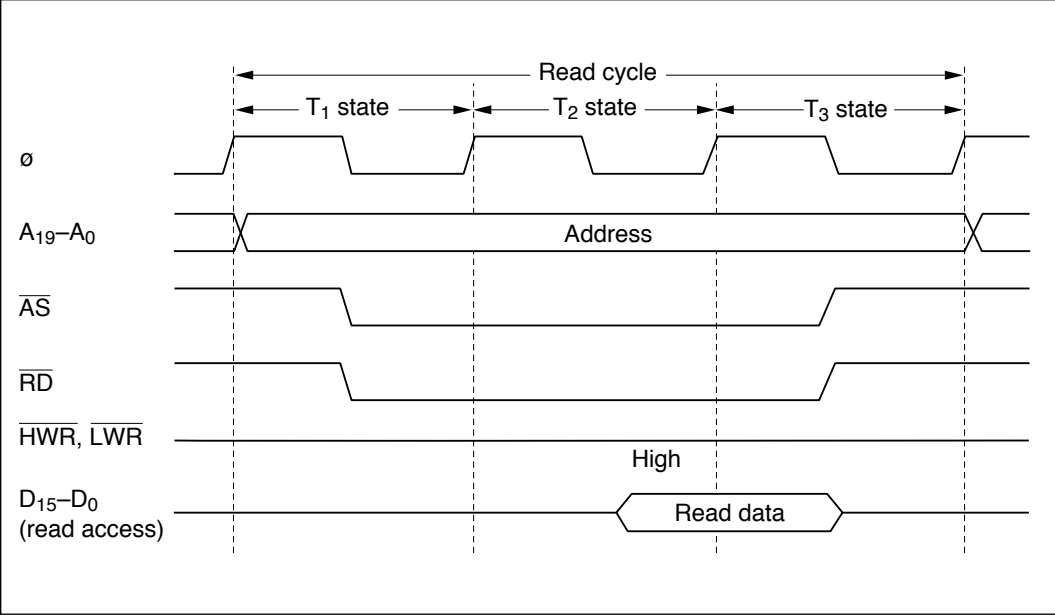

Figure 3-16 Read Access Cycle for Three-State-Access Address Space

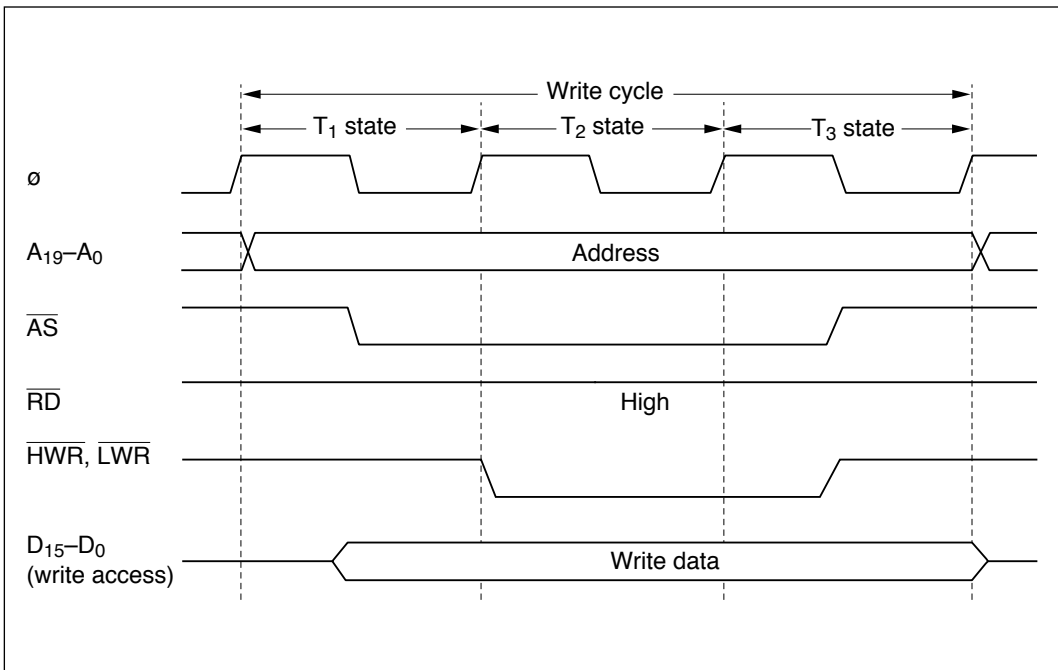

Figure 3-17 Write Access Cycle for Three-State-Access Address Space

3.10 CPU States

The H8/500 CPU has five processing states.

These states are described next.

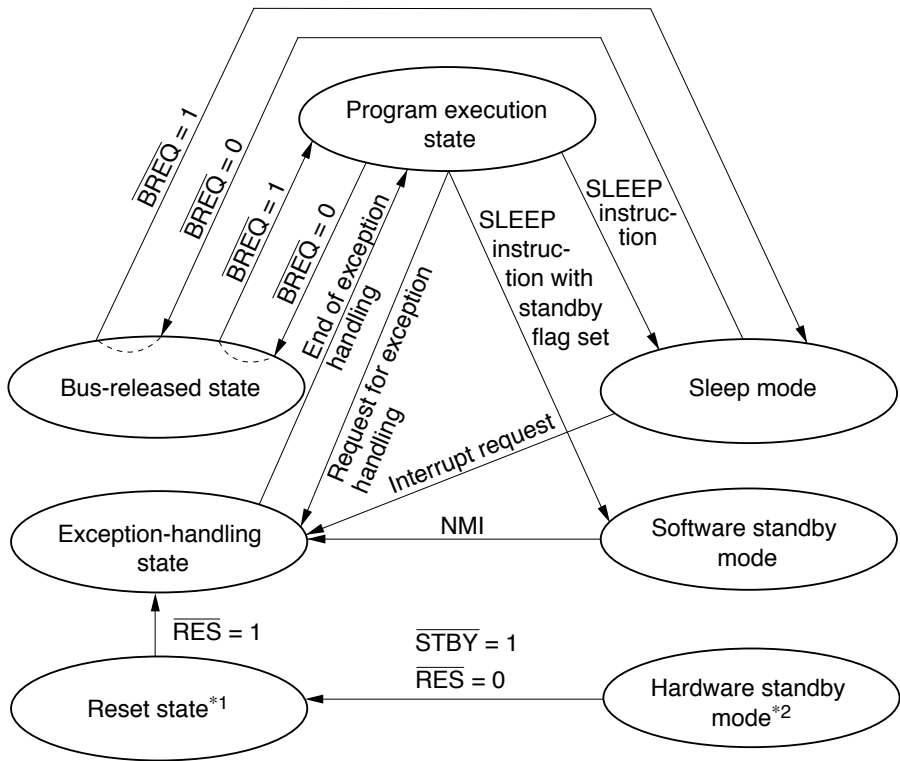

3.10.1 Overview

The five processing states of the H8/500 CPU are the program execution state, exception-handling state, bus-released state, reset state, and power-down state.

The power-down state is further divided into a sleep mode, software standby mode, and hardware standby mode. Table 3-9 summarizes these states. Figure 3-18 shows a map of the state transitions.

Table 3-9 Processing States

State		Description
Program execution state		The H8/500 CPU executes program instructions in sequence.
Exception-handling state		A transient state in which the H8/500 CPU executes a hardware sequence (saving the program counter and status register, fetching a vector, etc.) triggered by a reset, interrupt, or other exception.
Bus-released state		The H8/500 CPU has released the external bus in response to an external bus request signal.
Reset state		The H8/500 CPU and all on-chip supporting modules have been initialized and are stopped.
Power-down state	Sleep mode	Some or all clock signals are stopped to conserve power.
	Software standby mode	
	Hardware standby mode	

- Notes:
1. From any state except hardware standby mode, a transition to the reset state occurs whenever \overline{RES} goes low.
 2. From any state, a transition to hardware standby mode occurs when \overline{STBY} goes low.

Figure 3-18 State Transitions

3.10.2 Program Execution State

In this state the H8/500 CPU executes program instructions in normal sequence.

3.10.3 Exception-Handling State

The exception-handling state is a transient state that occurs when the H8/500 CPU alters the normal program flow due to an interrupt, trap instruction, address error, or other exception.

See section 4, “Exception Handling” for further information on the exception-handling state.

3.10.4 Bus-Released State

When so requested, the H8/500 CPU can grant control of the external bus to an external device. While an external device has the bus right, the H8/500 CPU is said to be in the bus-released state.

Granting of the bus is controlled by the $\overline{\text{BREQ}}$ and $\overline{\text{BACK}}$ signals. Bus requests are input at the $\overline{\text{BREQ}}$ pin. When the bus has been released, an acknowledging signal is output at the $\overline{\text{BACK}}$ pin.

Figure 3-19 illustrates the procedure for releasing the bus.

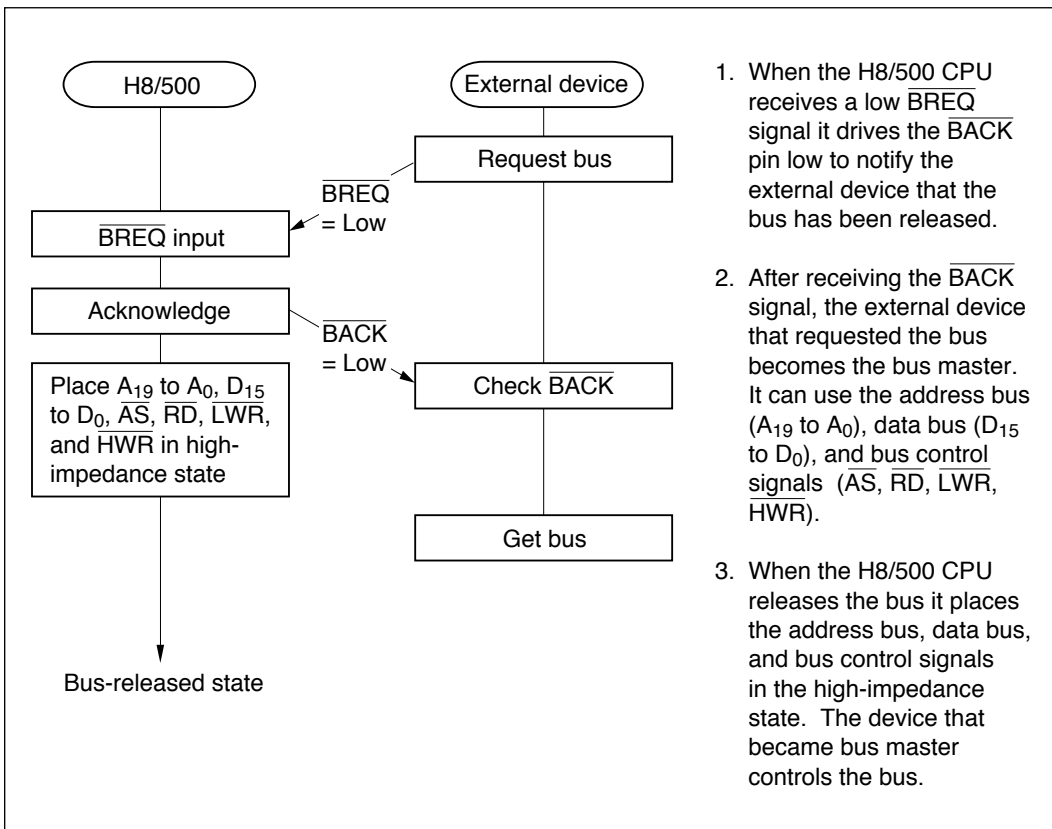

Figure 3-19 Bus Release Procedure

Bus Release Control Register (address H'FF1B): This register (BRCR) enables and disables $\overline{\text{BREQ}}$ input and $\overline{\text{BACK}}$ output. BRCR is initialized to H'FE by a reset and in hardware standby mode. It is not initialized in software standby mode. The BRCR bit structure is shown next.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	BRLE
Initial value	1	1	1	1	1	1	1	0
R/W	—	—	—	—	—	—	—	R/W
Reserved bits								Bus release enable bit Selects port A functions

Bits 7 to 1—Reserved: Read-only bits, always read as 1.

Bit 0—Bus Release Enable Bit (BRLE): Selects the functions of pins PA₆ and PA₅.

Bit 0

BRLE	Description
0	PA ₆ and PA ₅ are used for general-purpose input and output (Initial value)
1	PA ₆ is used for BACK output; PA ₅ is used for BREQ input

(1) Case in which $\overline{\text{BREQ}}$ is Acknowledged at End of Bus Cycle

Figure 3-20 shows the timing when the H8/500 CPU acknowledges the $\overline{\text{BREQ}}$ signal at the end of a bus cycle.

The $\overline{\text{BREQ}}$ signal is sampled during every instruction fetch cycle and data read or write cycle. If $\overline{\text{BREQ}}$ is low, the H8/500 CPU releases the bus at the end of the cycle. In word data access by means of two successive byte accesses, first to the upper byte, then to the lower byte (access to the eight-bit-bus-access address space or an on-chip supporting module), the H8/500 CPU does not release the bus right until it has accessed the lower byte.

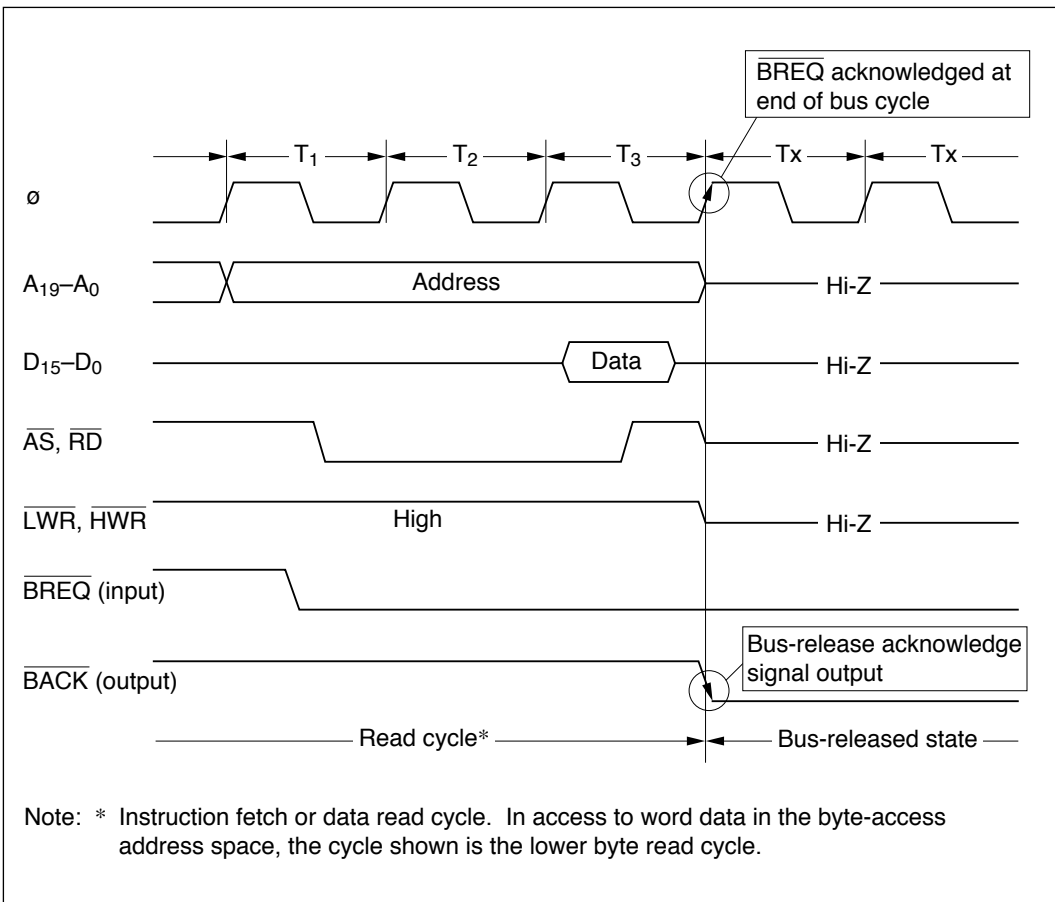

Figure 3-20 Case of $\overline{\text{BREQ}}$ Acknowledged at End of Bus Cycle (e.g., Read Cycle)

(2) Case in which $\overline{\text{BREQ}}$ is Acknowledged at End of Machine Cycle

Figure 3-21 shows the timing when the H8/500 CPU acknowledges the $\overline{\text{BREQ}}$ signal at the end of a machine cycle.

The H8/500 CPU acknowledges the $\overline{\text{BREQ}}$ signal at the end of machine cycles during execution of the MULXU or DIVXU instruction.

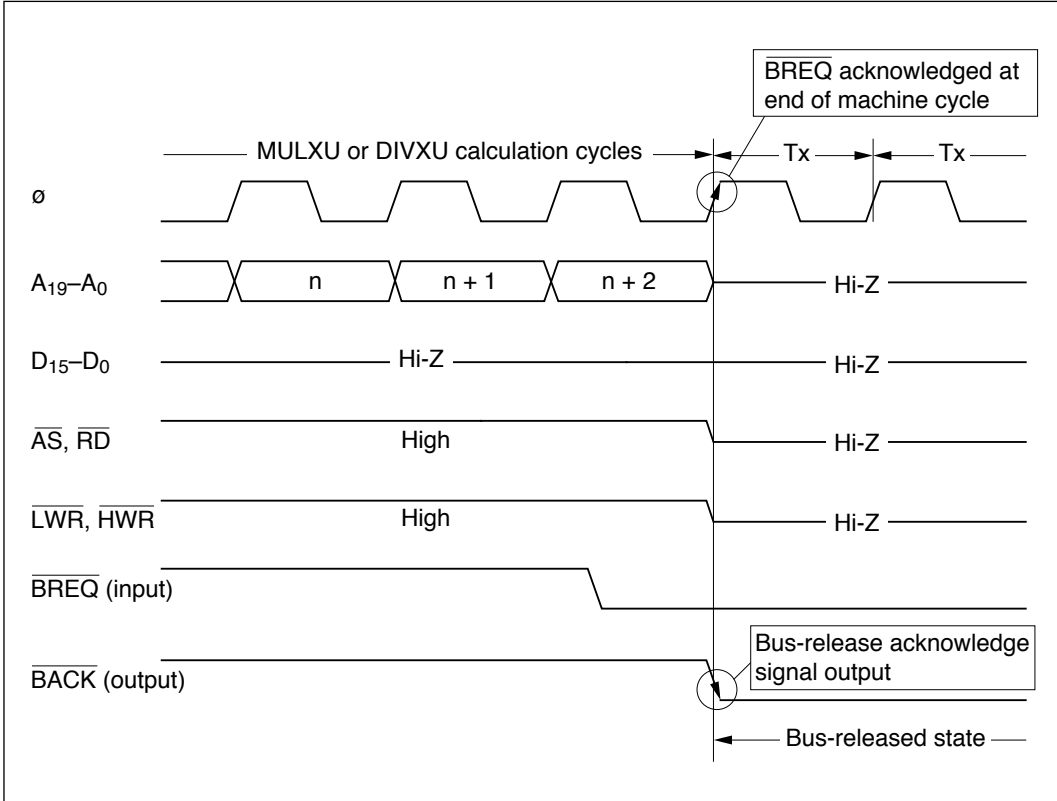

Figure 3-21 Case of $\overline{\text{BREQ}}$ Acknowledged at End of Machine Cycle (during Execution of MULXU or DIVXU Instruction)

(3) Case in which $\overline{\text{BREQ}}$ is Acknowledged in Sleep Mode

Figure 3-22 shows the timing when the H8/500 CPU acknowledges the $\overline{\text{BREQ}}$ signal in sleep mode.

The H8/500 CPU acknowledges the $\overline{\text{BREQ}}$ signal at any time during sleep mode.

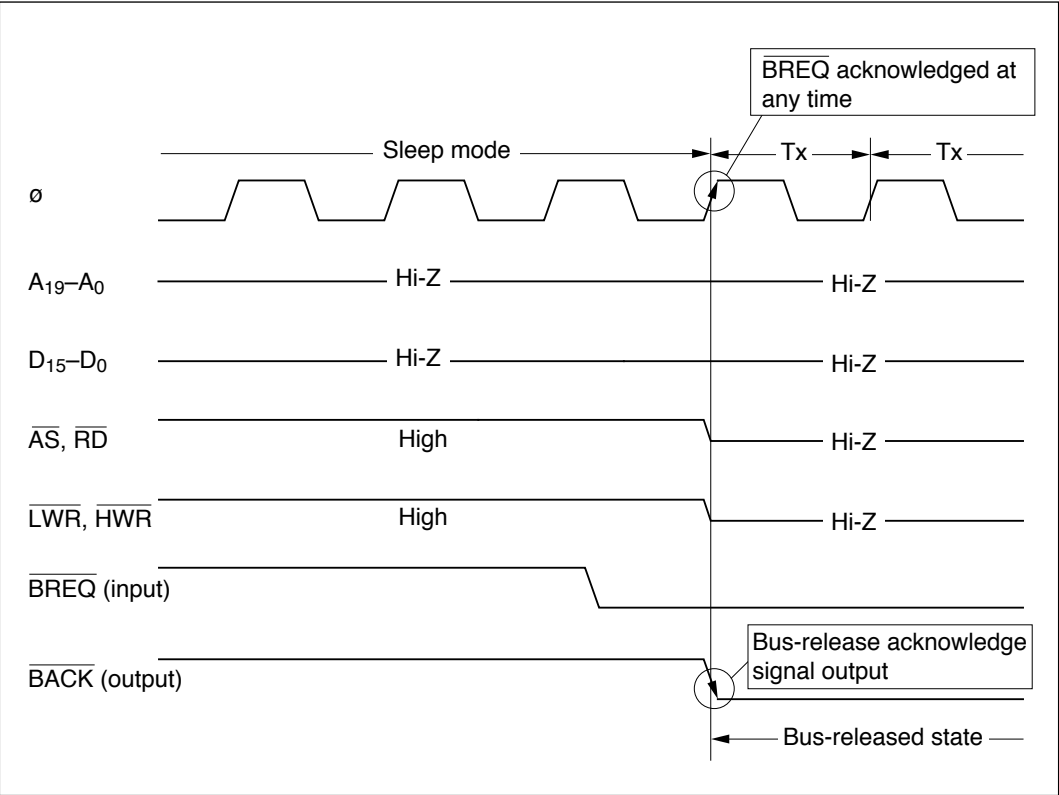

Figure 3-22 Case of $\overline{\text{BREQ}}$ Acknowledged in Sleep Mode

(4) Bus-Release Operation during Two-State Access

Figure 3-23 shows the timing when the bus is requested during a two-state access cycle.

When an external device requests the bus during two-state access, the H8/500 CPU enters the bus-released state as follows:

- ① The $\overline{\text{BREQ}}$ pin is sampled at the start of the T_1 state. If $\overline{\text{BREQ}}$ is low, at the end of the bus cycle the H8/500 CPU halts and enters the bus-released state.
- ② In the case of two-state access, at the end of the T_2 state the $\overline{\text{BACK}}$ signal goes low to indicate that the bus-released state has been entered. The address bus (A_{19} to A_0), data bus (D_{15} to D_0), and bus control signals ($\overline{\text{AS}}$, $\overline{\text{RD}}$, $\overline{\text{LWR}}$, $\overline{\text{HWR}}$) are placed in the high-impedance state.
- ③ While the bus is released, the H8/500 CPU constantly samples the $\overline{\text{BREQ}}$ pin (at each Tx state) and remains in the bus-released state while $\overline{\text{BREQ}}$ is low.
- ④ When $\overline{\text{BREQ}}$ goes high during a Tx state, at the end of the next state the H8/500 CPU drives the $\overline{\text{BACK}}$ signal high to indicate that it has regained possession of the bus (and that CPU cycles will resume).
- ⑤ CPU cycles resume at the end of the next state after $\overline{\text{BACK}}$ goes high.

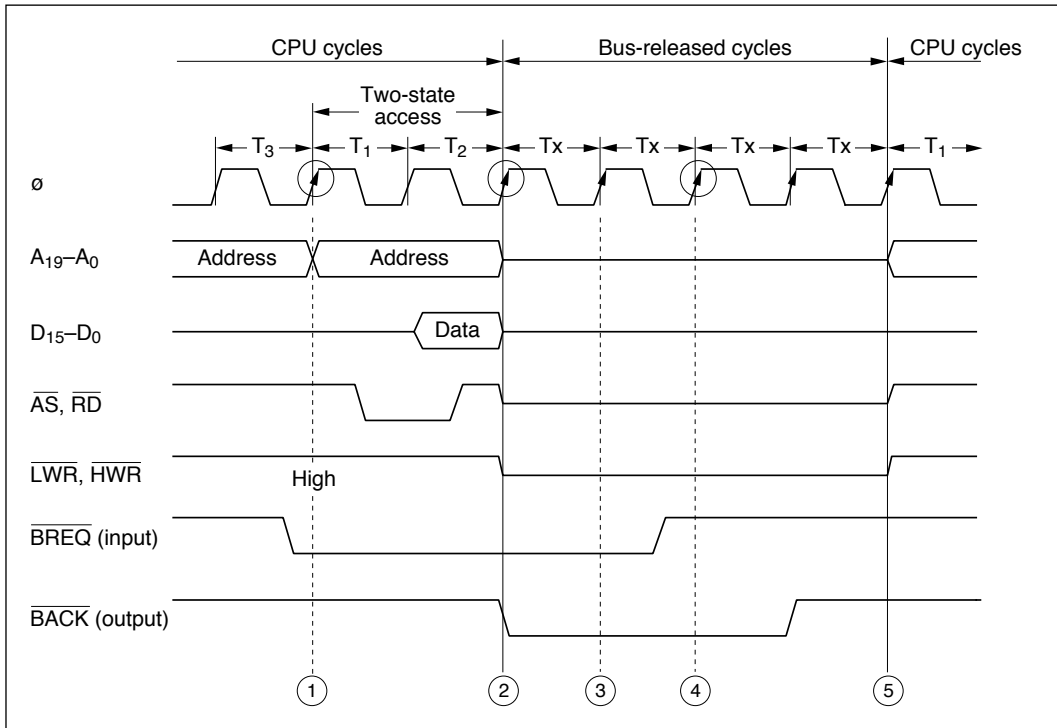

Figure 3-23 Bus Release during Two-State Access (e.g., Read Cycle)

(5) Bus-Release Operation during Three-State Access

Figure 3-24 shows the timing when the bus is requested during a three-state access cycle.

When an external device requests the bus during three-state access, the H8/500 CPU enters the bus-released state as follows:

- ① The $\overline{\text{BREQ}}$ pin is sampled at the start of the T_1 , T_2 , and T_W states. If $\overline{\text{BREQ}}$ is low, at the end of the bus cycle the H8/500 CPU halts and enters the bus-released state.
- ② In the case of three-state access, at the end of the T_3 state the $\overline{\text{BACK}}$ signal goes low to indicate that the bus-released state has been entered. The address bus (A_{19} to A_0), data bus (D_{15} to D_0), and bus control signals ($\overline{\text{AS}}$, $\overline{\text{RD}}$, $\overline{\text{LWR}}$, $\overline{\text{HWR}}$) are placed in the high-impedance state.
- ③ When $\overline{\text{BREQ}}$ goes high during a T_x state, at the end of the next state the H8/500 CPU drives the $\overline{\text{BACK}}$ signal high to indicate that it has regained possession of the bus (and that CPU cycles will resume).
- ④ CPU cycles resume at the end of the next state after $\overline{\text{BACK}}$ goes high.

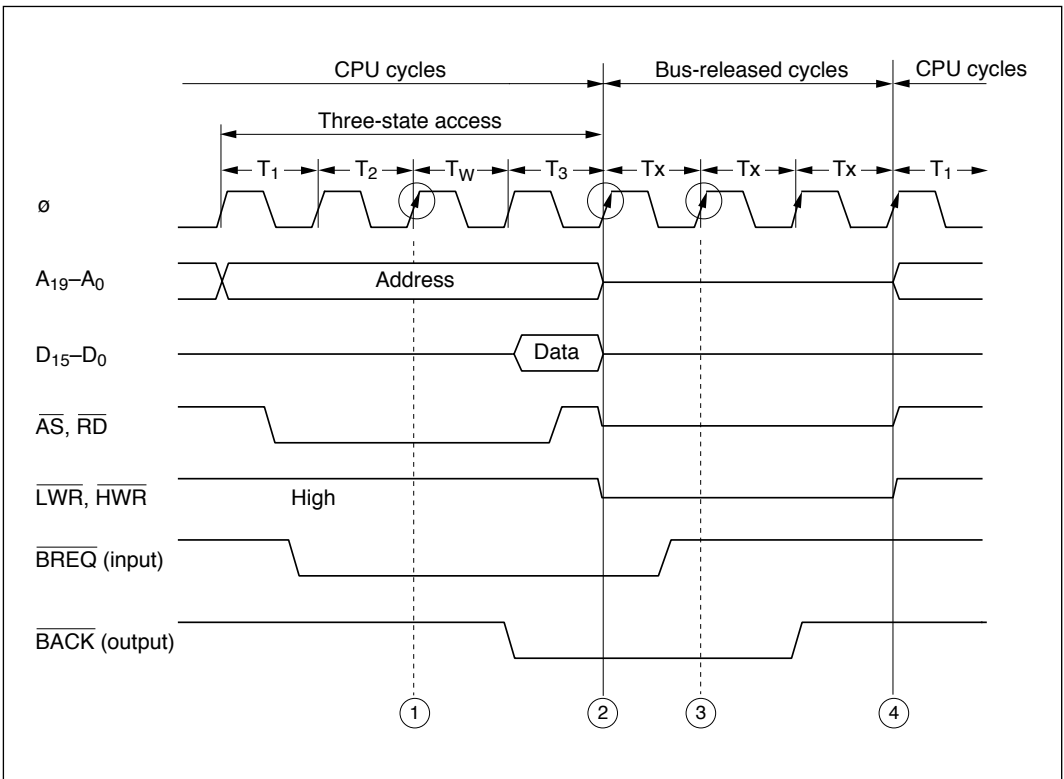

Figure 3-24 Bus Release during Three-State Access (e.g., Read Cycle)

(6) Bus-Release Operation during Internal CPU Operations

Figure 3-25 shows the timing when the bus is requested during internal CPU operations.

When an external device requests the bus during internal CPU operations, the H8/500 CPU enters the bus-released state as follows:

- ① The $\overline{\text{BREQ}}$ pin is sampled at the start of the T_1 state. If $\overline{\text{BREQ}}$ is low, at the end of the internal cycle the H8/500 CPU halts and enters the bus-released state.
- ② In the case of internal CPU operations, at the end of a T_1 state the $\overline{\text{BACK}}$ signal goes low to indicate that the bus-released state has been entered. The address bus (A_{19} to A_0), data bus (D_{15} to D_0), and bus control signals ($\overline{\text{AS}}$, $\overline{\text{RD}}$, $\overline{\text{LWR}}$, $\overline{\text{HWR}}$) are placed in the high-impedance state.
- ③ When $\overline{\text{BREQ}}$ goes high during a Tx state, at the end of the next state the H8/500 CPU drives the $\overline{\text{BACK}}$ signal high to indicate that it has regained possession of the bus (and that CPU cycles will resume).
- ④ CPU cycles resume at the end of the next state after $\overline{\text{BACK}}$ goes high.

Figure 3-25 Bus Release during Internal CPU Operation

(7) Notes

- The H8/500 CPU does not accept interrupts while in the bus-released state.
- The $\overline{\text{BREQ}}$ signal must be held low until $\overline{\text{BACK}}$ goes low. If $\overline{\text{BREQ}}$ returns to the high level before $\overline{\text{BACK}}$ goes low, the bus release operation may be executed incorrectly.

3.10.5 Reset State

In the reset state, the H8/500 CPU and all on-chip supporting modules are initialized and placed in the stopped state. The H8/500 CPU enters the reset state whenever the $\overline{\text{RES}}$ pin goes low, unless the H8/500 CPU is currently in the hardware standby mode.

See section 4.2, “Reset” for further information on the reset state.

3.10.6 Power-Down State

The power-down state comprises three power-down modes: sleep mode, software standby mode, and hardware standby mode.

See section 17, “Power-Down State” for further information.

Section 4 Exception Handling

4.1 Overview

There are five types of exceptions: reset, address error, trace, interrupt, and instruction exceptions. There are three types of instruction exceptions: invalid instruction, trap instruction, and DIVXU instruction with zero divisor.

Handling of these exceptions is described next.

4.1.1 Exception Handling Types and Priority

Table 4-1 lists the types of exception handling for exceptions other than instruction exceptions, and indicates their priority. The system assigns a reserved priority to each of these exception types. If two or more exceptions occur simultaneously, they are accepted and handled in priority order.

Table 4-2 lists the types of instruction exception handling. Instruction exceptions cannot occur simultaneously, so there is no priority order.

Table 4-1 Exception Types and Priority

Priority	Exception Type	Source	Start of Exception Handling
High	Reset	$\overline{\text{RES}}$ input	Rising edge of $\overline{\text{RES}}$ signal
	Address error	Invalid access (address error)	End of instruction execution
	Trace	Trace bit (T) = 1 in SR	End of instruction execution
	Interrupt	External or internal interrupt request	End of instruction execution or end of exception handling
Low			

Table 4-2 Instruction Exceptions

Exception Type	Source	Start of Exception Handling
Invalid instruction	Fetching of invalid instruction	Start of execution of instruction with undefined code
Trap instruction	Trap instruction	Start of execution of trap instruction
Zero divide	DIVXU instruction	Start of execution of DIVXU instruction with zero divisor

4.1.2 Exception Handling Operation

Exception handling can originate from a variety of sources.

Exception handling other than reset exception handling is described next. For reset exception handling, see section 4.2, “Reset.”

Figure 4-1 is a flowchart of the handling of exceptions other than a reset.

In minimum mode, the program counter (PC) and status register (SR) are saved on the stack. In maximum mode the code page register (CP), PC, and SR are saved on the stack. Next the T bit in the status register is cleared to 0, the start address corresponding to the exception source is read from the exception vector table, and program execution begins from the indicated address.

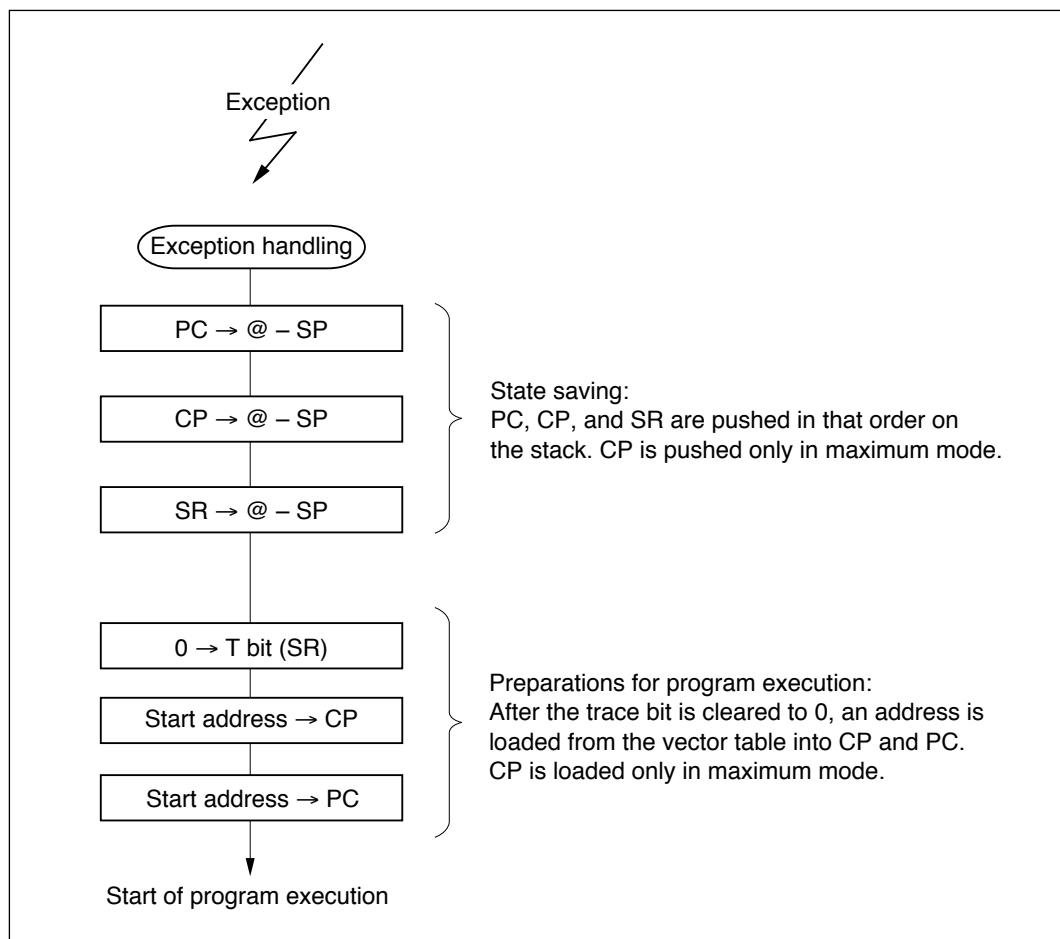

Figure 4-1 Exception Handling Flowchart

4.1.3 Exception Sources and Vector Table

Figure 4-2 classifies the exception sources. Table 4-3 shows the exception vector table. The vector addresses differ between minimum and maximum modes. In maximum mode the vector table is located in page 0. For internal interrupt vectors, see table 5-3, “Interrupt Priorities and Vector Addresses.”

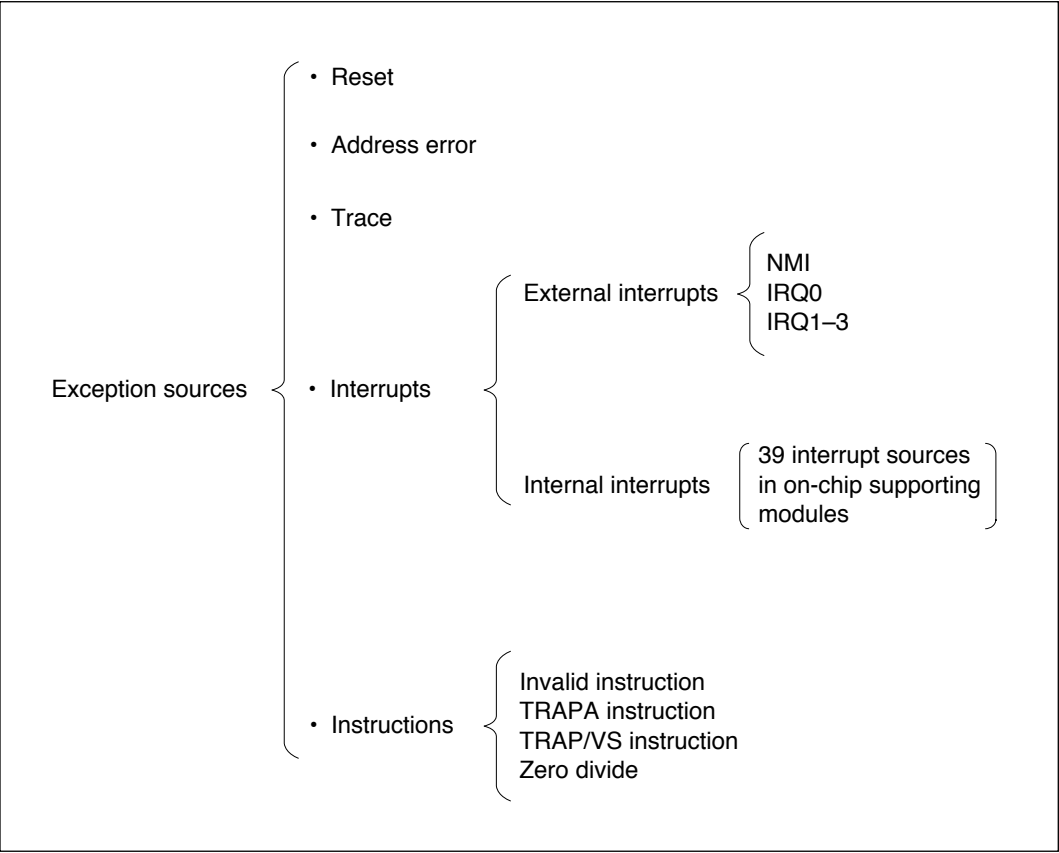

Figure 4-2 Classification of Exception Sources

Table 4-3 Exception Vector Table

Exception Source	Vector Address	
	Minimum Mode	Maximum Mode
Reset (initial PC value)	H'0000–H'0001	H'0000–H'0003
(Reserved for system)	H'0002–H'0003	H'0004–H'0007
Invalid instruction	H'0004–H'0005	H'0008–H'000B
DIVXU instruction (zero divisor)	H'0006–H'0007	H'000C–H'000F
TRAP/VS instruction	H'0008–H'0009	H'0010–H'0013
(Reserved for system)	H'000A–H'000B ⋮ H'000E–H'000F	H'0014–H'0017 ⋮ H'001C–H'001F
Address error	H'0010–H'0011	H'0020–H'0023
Trace	H'0012–H'0013	H'0024–H'0027
(Reserved for system)	H'0014–H'0015	H'0028–H'002B
External interrupt: NMI	H'0016–H'0017	H'002C–H'002F
(Reserved for system)	H'0018–H'0019 ⋮ H'001E–H'001F	H'0030–H'0033 ⋮ H'003C–H'003F
TRAPA instruction (16 sources)	H'0020–H'0021 ⋮ H'003E–H'003F	H'0040–H'0043 ⋮ H'007C–H'007F
External interrupt: IRQ0	H'0040–H'0041	H'0080–H'0083
WDT interval interrupt	H'0042–H'0043	H'0084–H'0087
External interrupts: IRQ1	H'0048–H'0049	H'0090–H'0093

Internal interrupts	H'0044–H'0045 H'0050–H'0051 ⋮ H'009E–H'009F	H'0088–H'008B H'00A0–H'00A3 ⋮ H'013C–H'013F

4.2 Reset

4.2.1 Overview

A reset has the highest exception priority.

Reset exception handling is described below.

When the $\overline{\text{RES}}$ pin goes low, all processing halts and the H8/538F enters the reset state. A reset initializes the internal state of the H8/500 CPU and the registers of on-chip supporting modules. When the $\overline{\text{RES}}$ pin rises from low to high, the H8/500 CPU begins reset exception handling.

4.2.2 Reset Sequence

The H8/538F enters the reset state when the $\overline{\text{RES}}$ pin goes low.

To ensure that the H8/538F is reset, the $\overline{\text{RES}}$ pin should be held low for at least 20 ms at power-up. To reset the H8/538F during operation, the $\overline{\text{RES}}$ pin should be held low for at least six system clock cycles (6ϕ).

See appendix E, “Pin States” for the states of the pins in the reset state.

When the $\overline{\text{RES}}$ pin rises to the high level after being held low for the necessary time, the H8/500 CPU begins reset exception handling. Figure 4-3 shows the sequence of operations at the end of the reset state.

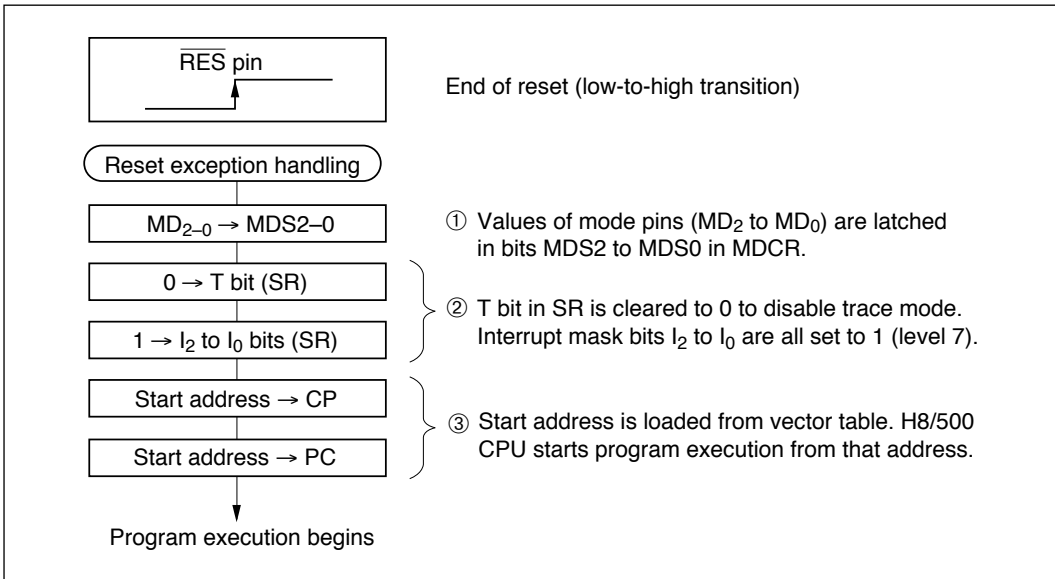

Figure 4-3 Reset Exception Handling Flowchart

The vector table contents differs between minimum and maximum mode. The vector table contents in each mode are described next.

(1) Minimum Mode: Figure 4-4 shows the reset vector in minimum mode.

In minimum mode the reset vector is located at addresses H'0000 and H'0001. When exception handling begins, the H8/500 CPU copies the reset vector into the program counter (PC). Program execution then starts from the PC address.

Figure 4-4 Reset Vector in Minimum Mode

Figure 4-5 shows the reset sequence in minimum mode.

Figure 4-5 shows the case in which the program area and stack area are both located in the eight-bit-bus three-state-access address space.

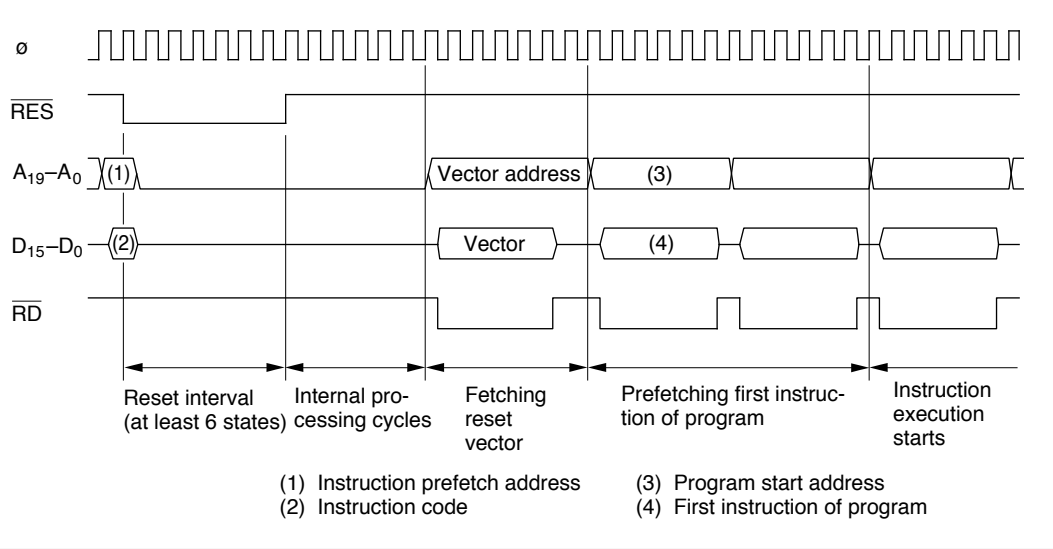

Figure 4-5 Reset Sequence in Minimum Mode

(2) **Maximum Mode:** Figure 4-6 shows the reset vector in maximum mode.

In maximum mode the reset vector is located at addresses H'0000 to H'0003. When exception handling begins, the H8/500 CPU copies the reset vector into the code page register (CP) and program counter (PC), ignoring the vector data at H'0000. Program execution then starts from the CP and PC address.

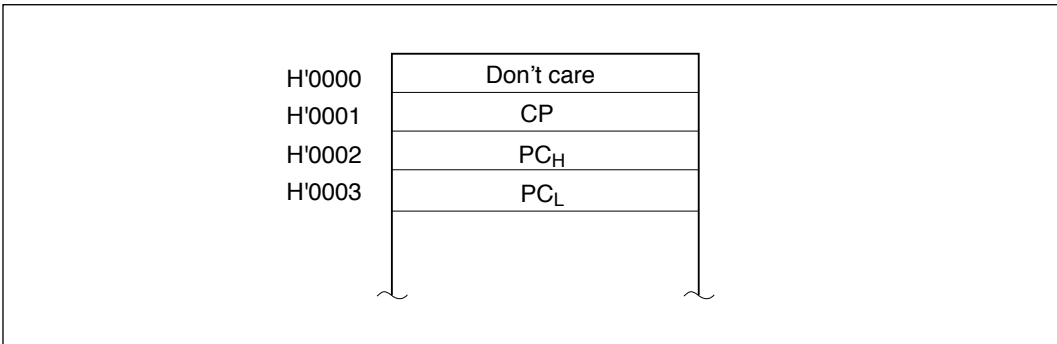

Figure 4-6 Reset Vector in Maximum Mode

Figure 4-7 shows the reset sequence in maximum mode.

Figure 4-7 shows the case in which the program area and stack area are both located in the 16-bit-bus two-state-access address space.

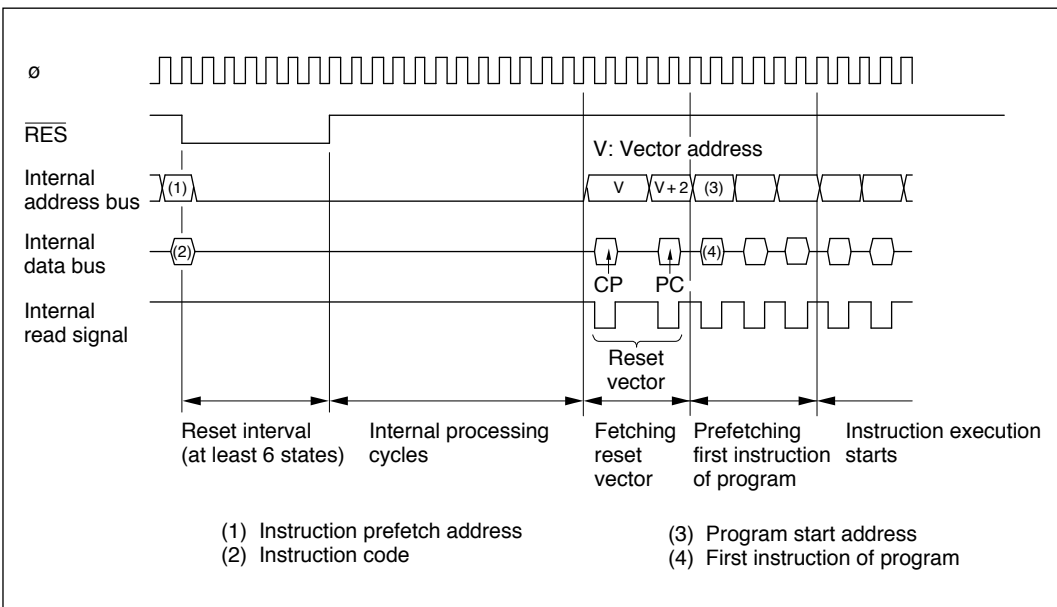

Figure 4-7 Reset Sequence in Maximum Mode

4.2.3 Interrupts after Reset

If an interrupt is accepted after a reset but before the stack pointer (SP) is initialized, the program counter and status register will not be saved correctly, leading to a program crash. This danger can be avoided as explained next.

When the chip comes out of the reset state all interrupts, including NMI, are disabled, so the first instruction is always executed. Crashes can be avoided by using this first instruction to initialize SP. In minimum mode, the first instruction after a reset should initialize SP. In maximum mode, the first instruction after a reset should initialize the stack page register (TP), and the next instruction should initialize SP.

Examples:

1. Minimum mode

```
.ORG H'0000
MOV.W   #H'FE80, SP
.
```

2. Maximum mode

```
.ORG H'0000
LDC.B   #H'00, TP
MOV.W   #H'FE80, SP
.
```

4.3 Address Error

An address error occurs when invalid access is attempted. There are three types of address errors:

1. Address error in instruction prefetch
2. Address error in word data access
3. Address error in single-chip mode

When an address error occurs, the H8/500 CPU begins address error exception handling and clears the T bit of the status register to 0. The interrupt mask level in bits I_2 to I_0 is not changed.

Each type of address error is described next.

4.3.1 Address Error in Instruction Prefetch

An attempt to prefetch an instruction from the on-chip registers at addresses H'FE80 to H'FFFF causes an address error.

The address error exception handling sequence for this case is:

The PC value pushed on the stack is the address of the instruction immediately following the last instruction executed.

Program code should not be located in addresses H'FE7D to H'FE7E. If program code is located in these addresses, instruction prefetch will be attempted in the on-chip register area, causing an address error.

Figure 4-8 shows the areas in which instruction prefetch leads to an address error.

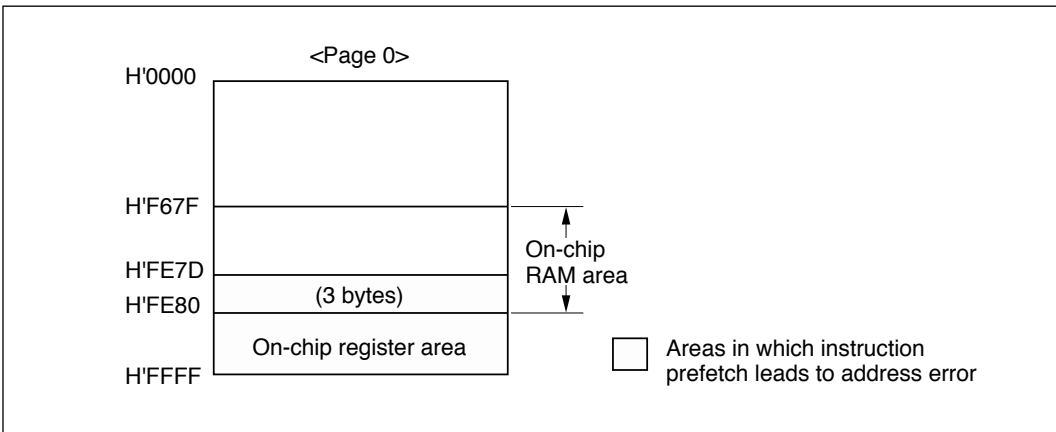

Figure 4-8 Areas in which Instruction Prefetch Leads to Address Error

4.3.2 Address Error in Word Data Access

An address error occurs if an attempt is made to access word data starting at an odd address. The PC value pushed on the stack is the address of the next instruction after the instruction that attempted to access word data at an odd address.

Figure 4-9 shows an example of illegal location of word data.

(Example) `MOV.W @2m+1, R0` causes an address error.

Figure 4-9 Example of Illegal Location of Word Data

4.3.3 Address Error in Single-Chip Mode

In single-chip mode there is no external memory, so in addition to the word access address errors described in section 4.3.2, address errors can occur due to access to missing areas in the address space.

(1) Access to Addresses H'EE80 to H'F67F: In single-chip mode these addresses form a missing address area; they are assigned neither to on-chip memory nor to on-chip registers.

Instruction prefetch, byte data access, or word data access in the missing address area causes an address error. An address error also occurs if an instruction is located in the last three bytes of on-chip ROM, because the H8/500 CPU will attempt to prefetch the next instruction from addresses H'EE80 to H'EE82 in the missing address area.

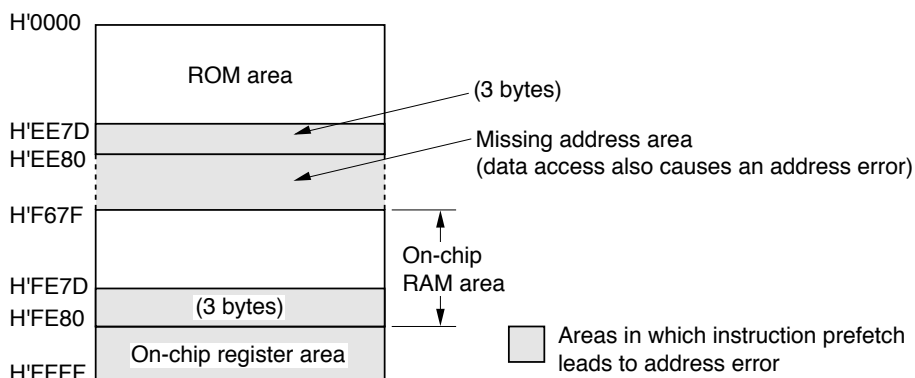

Figure 4-10 Areas in which Instruction Prefetch Leads to Address Error (Single-Chip Mode)

(2) Access to Disabled RAM Area: When the on-chip RAM area is disabled in single-chip mode, the missing address area extends from H'EE80 to H'FE7F. Instruction prefetch, byte data access, or word data access in this missing address area causes an address error. An address error also occurs if an instruction is located in the last three bytes of on-chip ROM, because the H8/500 CPU will attempt to prefetch the next instruction from addresses H'EE80 to H'EE82 in the missing address area.

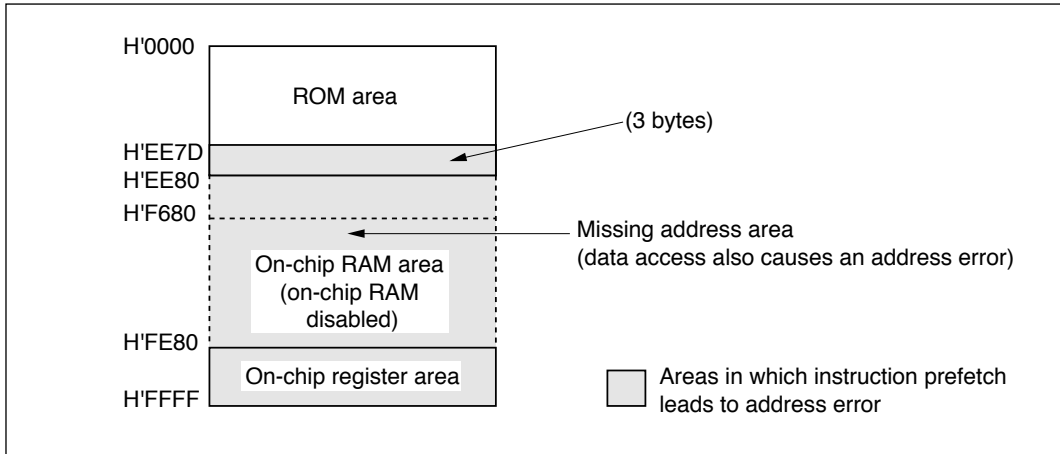

Figure 4-11 Areas in which Instruction Prefetch Leads to Address Error (Single-Chip mode with On-Chip RAM Disabled)

4.4 Trace

Trace mode can be used by a debug program, for example, to monitor the execution of a program under test.

(1) Trace Mode: When the trace bit (T bit) in the status register (SR) is set to 1, the H8/500 CPU operates in trace mode. A trace exception occurs at the completion of each instruction.

In trace exception handling the T bit in SR is cleared to 0 to disable trace mode. The interrupt mask level in bits I_2 to I_0 is not changed, however; interrupts are accepted during trace exception handling.

The trace exception-handling routine should end with an RTE instruction. When the trace routine returns with the RTE instruction, the status register is popped from the stack and trace mode resumes.

(2) Contention with Address Error Exception Handling: Address error exception handling occurs at the end of a bus cycle, so it does not normally conflict with trace exception handling. One instruction is always executed after exception handling, however, so contention may occur at this point, requiring special consideration.

If address error and trace exceptions both occur at the end of an instruction, because of the priority relationship between these exceptions, address error exception handling is carried out. Trace mode is disabled during execution of the instruction that caused the address error and during the address error exception handling routine. After return from address error exception handling, one instruction is executed, then trace mode resumes.

4.5 Interrupts

There are five external sources of interrupt exception handling ($\overline{\text{NMI}}$, $\overline{\text{IRQ}}_0$, $\overline{\text{IRQ}}_1$, $\overline{\text{IRQ}}_2$, $\overline{\text{IRQ}}_3$) and 39 sources in the on-chip supporting modules. Table 4-4 classifies the interrupt sources. The on-chip supporting modules that can request interrupts are the 16-bit integrated timer pulse unit (IPU), serial communication interfaces 1 and 2 (SCI1 and SCI2), A/D converter, and watchdog timer (WDT).

NMI is the highest-priority interrupt and is always accepted. The other 43 interrupt sources are controlled by the interrupt controller. The interrupt controller arbitrates between simultaneous interrupts by means of internal registers in which interrupt priorities are assigned to each module.

The interrupt priorities are set in interrupt priority registers A to F (IPRA to IPRF) in the interrupt controller. An interrupt priority level from 7 to 0 can be assigned to $\overline{\text{IRQ}}_0$. A single priority level from 7 to 0 can be assigned collectively to $\overline{\text{IRQ}}_1$, $\overline{\text{IRQ}}_2$, and $\overline{\text{IRQ}}_3$. Independent priority levels from 7 to 0 can also be assigned to each of the on-chip supporting modules.

The interrupt controller also controls the starting of the data transfer controller (DTC) in response to an interrupt. The DTC can transfer data in either direction between memory and I/O without using the CPU.

Whether to start the DTC can be selected on an individual interrupt basis in data transfer enable registers A to F (DTEA to DTEF) in the interrupt controller. The DTC is started if the corresponding bit in DTEA to DTEF is set to 1. If this bit is cleared to 0, interrupt exception handling is carried out. A few interrupts, including NMI, cannot start the DTC. The CPU halts during DTC operation.

For details of DTC interrupts, see section 6, “Data Transfer Controller.” Interrupt controller functions are detailed in section 5, “Interrupt Controller.”

Table 4-4 Interrupt Sources

Interrupt Category		Number of Sources
External interrupts	NMI	1
	IRQ0	1
	IRQ1–IRQ3	3
Internal interrupts	IPU	29
	SCI1	4
	SCI2	4
	A/D converter	1
	WDT	1

4.6 Invalid Instructions

An invalid instruction is an instruction with an undefined operation code or illegal addressing mode. If an attempt is made to execute an invalid instruction, the H8/500 CPU starts invalid instruction exception handling. The PC value pushed on the stack is the value of the program counter when the invalid instruction code was detected.

In the invalid instruction exception-handling sequence the T bit of the status register is cleared to 0, but the interrupt mask level (I_2 to I_0) is not changed.

4.7 Trap Instructions and Zero Divide

When the TRAPA or TRAP/VS instruction is executed, the H8/500 CPU starts trap exception handling. If an attempt is made to execute a DIVXU instruction with a zero divisor, the H8/500 CPU starts zero divide exception handling.

In the exception-handling sequences for these exceptions the T bit of the status register is cleared to 0, but the interrupt mask level (I_2 to I_0) is not changed.

If a normal interrupt is requested during execution of a trap or zero-divide instruction, interrupt handling begins after the exception-handling sequence for the trap or zero-divide instruction has been executed.

(1) TRAPA Instruction: When the TRAPA instruction is executed, the H8/500 CPU starts exception handling according to the CPU operating mode.

The TRAPA instruction includes a vector number from 0 to 15. The start address is read from the corresponding location in the vector table.

(2) TRAP/VS Instruction: When the TRAP/VS instruction is executed, the H8/500 CPU starts exception handling if the overflow (V) flag in the condition code register (CCR) is set to 1.

If the V flag is cleared to 0, no exception occurs and the next instruction is executed.

(3) DIVXU Instruction with Zero Divisor: The H8/500 CPU starts exception handling if an attempt is made to divide by zero in a DIVXU instruction.

4.8 Cases in which Exception Handling is Deferred

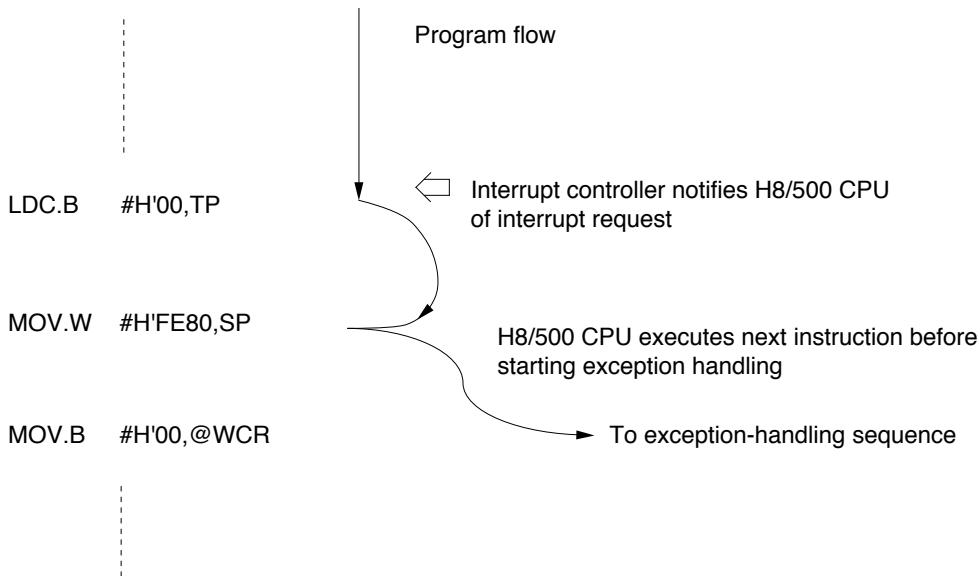

Exception handling of address errors, trace exceptions, external interrupt requests (NMI, $\overline{\text{IRQ}}_0$, $\overline{\text{IRQ}}_1$, $\overline{\text{IRQ}}_2$, $\overline{\text{IRQ}}_3$), and internal interrupt requests (39 sources) is not carried out immediately after execution of an interrupt-disabling instruction, reset exception, or data transfer cycle, but is deferred until after the next instruction has been executed.

4.8.1 Instructions that Disable Exception Handling

Interrupts are disabled immediately after the execution of five instructions: XORC, ORC, ANDC, LDC, and RTE.

After executing one of these instructions, the H8/500 CPU always executes the next instruction. If the next instruction is also one of these five, the next instruction after that is executed too. Exception handling starts after the next instruction that is not one of these five has been executed. See the following example.

Example:

4.8.2 Disabling of Exceptions Immediately after a Reset

After carrying out reset exception handling, the H8/500 CPU always executes the initial instruction.

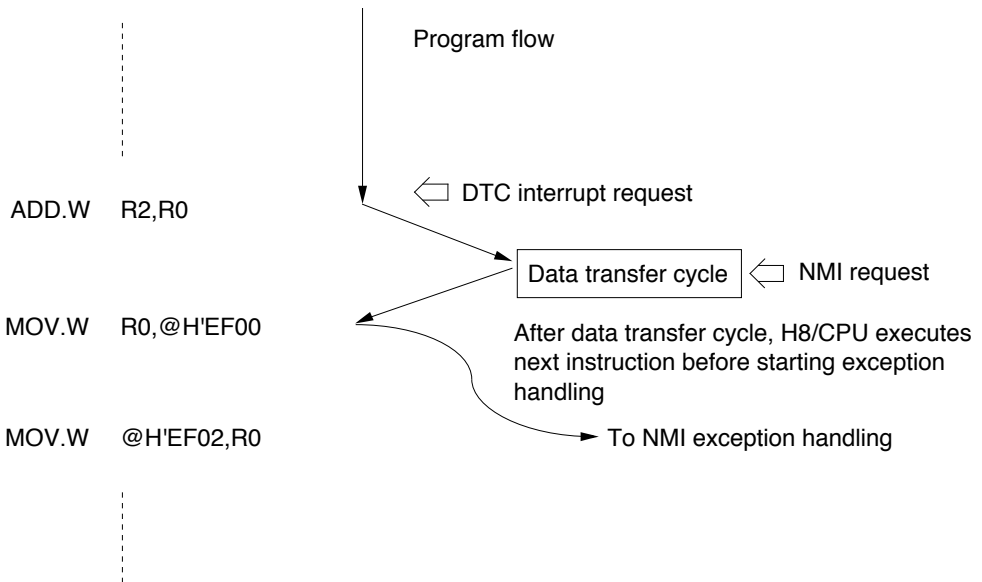

If an interrupt is accepted after a reset but before SP is initialized, the program counter and status register will not be saved correctly, leading to a program crash. To prevent this, in minimum mode the first instruction after a reset should initialize SP. In maximum mode, the first instruction after a reset should be an LDC instruction initializing TP, and the next instruction should initialize SP.

4.8.3 Disabling of Interrupts after a Data Transfer Cycle

If an interrupt starts the data transfer controller and a second interrupt is requested during the data transfer cycle, when the data transfer cycle ends, the H8/500 CPU always executes the next instruction before handling the second interrupt.

Even if a nonmaskable interrupt (NMI) occurs during a data transfer cycle, it is not accepted until the next instruction has been executed. An example is shown next.

Example:

4.9 Stack Status after Completion of Exception Handling

The status of the stack after exception handling is described next.

Table 4-5 shows the stack after completion of exception handling for various types of exceptions in minimum and maximum modes.

Table 4-5 Stack after Exception Handling

Exception Source	Minimum Mode	Maximum Mode
Trace, interrupt, trap instruction, DIVXU (zero divide)	<div>SP▸<div>SR (upper 8 bits) SR (lower 8 bits) Next instruction address (upper 8 bits) Next instruction address (lower 8 bits)</div></div>	<div>TP:SP▸<div>SR (upper 8 bits) SR (lower 8 bits) Don't care Next instruction page address (8 bits) Next instruction address (upper 8 bits) Next instruction address (lower 8 bits)</div></div>

Note: The RTE instruction returns to the next instruction after the instruction being executed when the exception occurred.

Invalid instruction	<div>SP▸<div>SR (upper 8 bits) SR (lower 8 bits) PC (upper 8 bits) when error occurred PC (lower 8 bits) when error occurred</div></div>	<div>TP:SP▸<div>SR (upper 8 bits) SR (lower 8 bits) Don't care CP (8 bits) when error occurred PC (upper 8 bits) when error occurred PC (lower 8 bits) when error occurred</div></div>
---------------------	---	---

Note: The CP and PC values pushed on the stack are not necessarily the address of the first byte of the invalid instruction.

Address error	<div>SP▸<div>SR (upper 8 bits) SR (lower 8 bits) PC (upper 8 bits) when error occurred PC (lower 8 bits) when error occurred</div></div>	<div>TP:SP▸<div>SR (upper 8 bits) SR (lower 8 bits) Don't care CP (8 bits) when error occurred PC (upper 8 bits) when error occurred PC (lower 8 bits) when error occurred</div></div>
---------------	---	---

Note: The CP and PC values pushed on the stack are the address of the next instruction after the last instruction successfully executed.

4.9.1 PC Value Pushed on Stack for Trace, Interrupts, Trap Instructions, and Zero Divide Exceptions

The PC value pushed on the stack for a trace, interrupt, trap, or zero divide exception is the address of the next instruction at the time when the interrupt was accepted.

4.9.2 PC Value Pushed on Stack for Address Error and Invalid Instruction

The PC value pushed on the stack for an address error or invalid instruction exception differs depending on the conditions when the exception occurs.

4.10 Notes on Use of the Stack

When using the stack, pay attention to the following points. Mistakes may lead to address errors when the stack is accessed, or may cause system crashes.

1. Always set SP on an even address.

If SP indicates an odd address, an address error will occur when the H8/500 CPU accesses the stack during interrupt handling or for a subroutine call. To keep SP pointing to an even address, always use word data size when saving or restoring register data or other data to or from the stack.

2. @-SP and @SP+ addressing modes

To keep SP pointing to an even address, in the @-SP and @SP+ addressing modes the H8/500 CPU performs word access even if the instruction specifies byte size.

This is not true in the @-Rn (pre-decrement) and @Rn+ (post-increment) addressing modes when Rn is a register from R0 to R6.

Section 5 Interrupt Controller

5.1 Overview

The interrupt controller decides when to start interrupt exception handling and when to start the data transfer controller (DTC), and arbitrates between competing interrupts. This section describes the interrupts and the functions, features, internal structure, and registers of the interrupt controller.

For details of data transfers performed by the DTC, see section 6, “Data Transfer Controller.”

5.1.1 Features

The features of the interrupt controller are:

- Six interrupt priority registers (IPR)

Priority levels from 7 to 0 can be assigned to IRQ0, IRQ1 to IRQ3, and each of the on-chip supporting modules, covering all interrupts except NMI.

- Default priority order for simultaneous interrupts on the same level

Lower-priority interrupts remain pending until higher-priority interrupts have been handled. NMI has the highest priority level (8) and cannot be masked.*

- Six data transfer enable (DTE) registers

Software can select which interrupts (other than NMI) to have served by the DTC.

Note: * NMI is masked under certain conditions in on-board programming mode, however. For details, see section 16.4.9, “NMI Input Masking.”

5.1.2 Block Diagram

Figure 5-1 shows a block diagram of the interrupt controller.

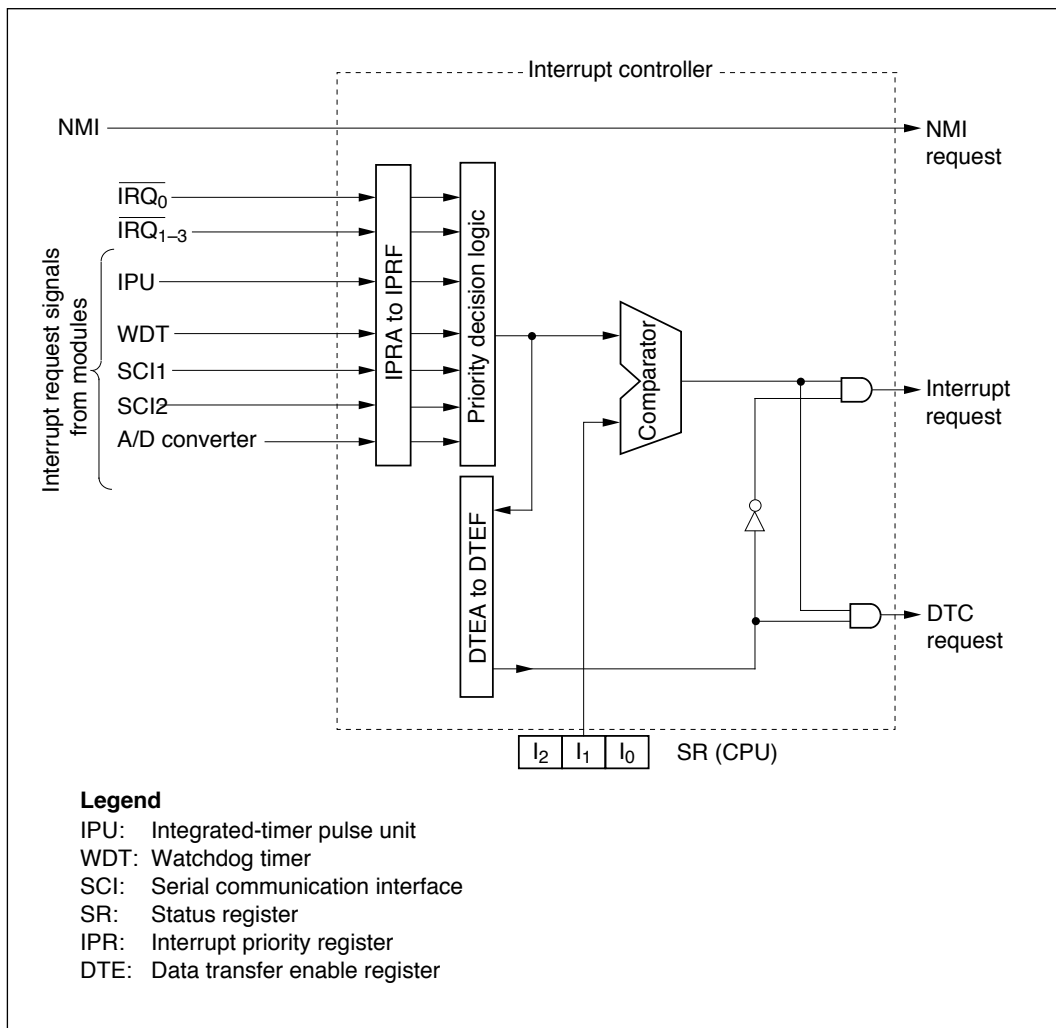

Figure 5-1 Block Diagram

5.1.3 Register Configuration

The interrupt controller has six interrupt priority registers (IPRA to IPRF) and six data transfer enable registers (DTEA to DTEF). See section 6.2.5, “Data Transfer Enable Registers A to F” for details of DTEA to DTEF.

Table 5-1 summarizes these registers.

Table 5-1 Interrupt Controller Registers

Address	Name	Abbreviation	R/W	Initial Value
H'FF00	Interrupt priority register A	IPRA	R/W	H'00
H'FF01	Interrupt priority register B	IPRB	R/W	H'00
H'FF02	Interrupt priority register C	IPRC	R/W	H'00
H'FF03	Interrupt priority register D	IPRD	R/W	H'00
H'FF04	Interrupt priority register E	IPRE	R/W	H'00
H'FF05	Interrupt priority register F	IPRF	R/W	H'00
H'FF08	Data transfer enable register A	DTEA	R/W	H'00
H'FF09	Data transfer enable register B	DTEB	R/W	H'00
H'FF0A	Data transfer enable register C	DTEC	R/W	H'00
H'FF0B	Data transfer enable register D	DTED	R/W	H'00
H'FF0C	Data transfer enable register E	DTEE	R/W	H'00
H'FF0D	Data transfer enable register F	DTEF	R/W	H'00

Table 5-2 summarizes the NMI control register (NMICR), IRQ control register (IRQCR), and IRQ flag register (IRQFR).

Table 5-2 Interrupt Controller Registers

Address	Name	Abbreviation	R/W	Initial Value
H'FF1C	NMI control register	NMICR	R/W	H'FE
H'FF1D	IRQ control register	IRQCR	R/W	H'F0
H'FEDE	IRQ flag register	IRQFR	R/W	H'F1

5.2 Interrupt Sources

There are two types of interrupts: external interrupts (NMI, IRQ0, IRQ1 etc.), and internal interrupts (39 sources). Table 5-3 indicates the default priority order and vector addresses of these interrupts.

When multiple interrupts occur simultaneously, the interrupt with the highest priority is served first. Using IPRA to IPRF, software can assign priorities to interrupts on a module basis. Relative priorities within the same module are fixed. If the same priority is assigned to two or more modules, simultaneous interrupt requests from those modules are served in the priority order in table 5-3.

After a reset, all interrupts except NMI are assigned priority 0 and are disabled.

Table 5-3 Interrupt Priorities and Vector Addresses

Interrupt Source		Assignable Priority Levels (initial value)	IPR Bits	Priority within Module	Vector Table Entry Address		Priority among Interrupts on Same Level
					Minimum Mode	Maximum Mode	
NMI		8 (8)	—	—	H'0016–0017	H'002C–002F	<div>High</div> <div>↑</div> <div>↓</div> <div>Low</div>

	OVI		4 bits	0	H'008E–008F	H'011C–011F	
SCI1	ERI1	7–0 (0)	IPRF	3	H'0090–0091	H'0120–0123	
	RI1		upper	2	H'0092–0093	H'0124–0127	
	TI1		4 bits	1	H'0094–0095	H'0128–012B	
	TEI1			0	H'0096–0097	H'012C–012F	
SCI2	ERI1	7–0 (0)	IPRF	3	H'0098–0099	H'0130–0133	
	RI1		lower	2	H'009A–009B	H'0134–0137	
	TI1		4 bits	1	H'009C–009D	H'0138–013B	
	TEI2			0	H'009E–009F	H'013C–013F	

The five external interrupts are NMI and IRQ0 to IRQ3.

Each external interrupt is described below.

5.2.1 NMI

NMI has the highest interrupt priority level (8) and cannot be masked. Input at the NMI pin is edge-sensed. Either the rising edge or falling edge can be selected by setting or clearing the nonmaskable interrupt edge bit (NMIEG) in the NMI control register (NMICR).

In NMI exception handling the T bit in the status register (SR) is cleared to 0 and I₂ to I₀ are all set to 1, thereby setting the interrupt mask level to 7.

NMI Control Register (Address H'FF1C): The NMI control register (NMICR) selects the sensitive edge of the NMI input. NMICR is initialized to H'FE by a reset and in hardware standby mode. It is not initialized in software standby mode. The NMICR bit structure is shown next.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	NMIEG
Initial value	1	1	1	1	1	1	1	0
R/W	—	—	—	—	—	—	—	R/W

Reserved bits

Nonmaskable interrupt edge
Selects sensitive edge of NMI input

(1) **Bits 7 to 1—Reserved:** Read-only bits, always read as 1.

(2) **Bit 0—Nonmaskable Interrupt Edge (NMIEG):** Selects the sensitive edge of the NMI input.

Bit 0	
NMIEG	Description
0	NMI is requested on falling edge of NMI input (Initial value)
1	NMI is requested on rising edge of NMI input

5.2.2 IRQ0

An IRQ0 interrupt can be requested by an interrupt signal from the $\overline{\text{IRQ}}_0$ pin or an interrupt signal from the watchdog timer (WDT). These two interrupt sources have different vectors.

The interrupt from the $\overline{\text{IRQ}}_0$ pin is level-sensed. A low $\overline{\text{IRQ}}_0$ input requests an IRQ0 interrupt if the interrupt request enable 0 bit (IRQ0E) in the IRQ control register (IRQCR) is set to 1. A WDT overflow requests an IRQ0 interrupt when the WDT is set to interval timer mode. The WDT then requests an IRQ0 interrupt each time the timer counter (TCNT) overflows.

A priority level from 7 to 0 can be assigned to IRQ0 in the upper four bits of IPRA. If bit 4 in DTEA is set to 1, IRQ0 is served by the DTC.

In IRQ0 exception handling the T bit in SR is cleared to 0 and the interrupt mask level is set to the value selected in the four upper bits of IPRA.

5.2.3 IRQ1 to IRQ3

Interrupts IRQ1 to IRQ3 are requested by interrupt signals from the $\overline{\text{IRQ}}_1$ to $\overline{\text{IRQ}}_3$ pins. The $\overline{\text{IRQ}}_1$ to $\overline{\text{IRQ}}_3$ inputs are sensed on the falling edge. The falling edge generates an IRQ1, IRQ2, or IRQ3 interrupt request if the interrupt request enable 1, 2, or 3 bit (IRQ1E, IRQ2E, or IRQ3E) in the IRQ control register (IRQCR) is set to 1.

A priority level from 7 to 0 can be assigned to IRQ1, IRQ2, and IRQ3 collectively in the lower four bits of IPRA. If bits 2 to 0 in DTEA are set, these interrupts are served by the DTC.

In IRQ1, IRQ2, and IRQ3 exception handling the T bit in SR is cleared to 0 and the interrupt mask level is set to the value selected in the lower four bits of IPRA.

IRQ Control Register (Address H'FF1D): The IRQ control register (IRQCR) enables and disables inputs at $\overline{\text{IRQ}}_3$, $\overline{\text{IRQ}}_2$, $\overline{\text{IRQ}}_1$, and $\overline{\text{IRQ}}_0$. IRQCR is initialized to H'F0 by a reset and in hardware standby mode. It is not initialized in software standby mode. The bit structure of IRQCR is shown next.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	IRQ3E	IRQ2E	IRQ1E	IRQ0E
Initial value	1	1	1	1	0	0	0	0
R/W	—	—	—	—	R/W	R/W	R/W	R/W

Reserved bits

Interrupt request enable bits

These bits select functions of pins in ports 6 and 7

(1) **Bits 7 to 4—Reserved:** Read-only bits, always read as 1.

(2) **Bit 3—Interrupt Request 3 Enable (IRQ3E):** Selects the function of pin P6₁.

Bit 3

IRQ3E	Description
0	P6 ₁ is used for general-purpose input and output (Initial value)
1	P6 ₁ is used for $\overline{\text{IRQ}}_3$ input

(3) **Bit 2—Interrupt Request 2 Enable (IRQ2E):** Selects the function of pin P6₀.

Bit 2

IRQ2E	Description
0	P6 ₀ is used for general-purpose input and output (Initial value)
1	P6 ₀ is used for $\overline{\text{IRQ}}_2$ input

(4) **Bit 1—Interrupt Request 1 Enable (IRQ1E):** Selects the function of pin P7₁.

Bit 1

IRQ1E	Description
0	P7 ₁ is used for general-purpose input and output (Initial value)
1	P7 ₁ is used for $\overline{\text{IRQ}}_1$ input

(5) **Bit 0—Interrupt Request 0 Enable (IRQ0E):** Selects the function of pin P7₀.

Bit 0

IRQ0E	Description
0	P7 ₀ is used for general-purpose input and output (Initial value)
1	P7 ₀ is used for $\overline{\text{IRQ}}_0$ input

IRQ Flag Register (address H'FEDE): The IRQ flag register (IRQFR) indicates the presence of IRQ3, IRQ2, and IRQ1 interrupt requests. When IRQ3, IRQ2, or IRQ1 is requested by external input, the H8/500 CPU sets the interrupt request 1, 2, or 3 flag (IRQ3F, IRQ2F, or IRQ1F) to 1. The interrupt request can be cleared by reading this flag after it has been set to 1, then writing 0. The H8/500 CPU clears IRQ3F, IRQ2F, or IRQ1F to 0 when it outputs the interrupt vector.

IRQFR is initialized to H'F1 by a reset and in hardware standby mode. It is not initialized in software standby mode. The bit structure of IRQFR is shown next.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	IRQ3F	IRQ2F	IRQ1F	—
Initial value	1	1	1	1	0	0	0	1
R/W	—	—	—	—	R/W*	R/W*	R/W*	—

Reserved bits

Interrupt request flags
These bits indicate
interrupt request input

Reserved bit

Note: * Software can write 0 to clear the flag.

- (1) **Bits 7 to 4—Reserved:** Read-only bits, always read as 1.
- (2) **Bit 3—Interrupt Request 3 Flag (IRQ3F):** Indicates that interrupt request 3 (IRQ3) has been input.

Bit 3

IRQ3F	Description
0	Interrupt request 3 (IRQ3) has not been input (Initial value)
1	Interrupt request 3 (IRQ3) has been input and is waiting for interrupt service (Clearing conditions) 1. Cleared automatically when the H8/500 CPU accepts IRQ3 and the interrupt vector is output 2. Can also be cleared by reading 1, then writing 0, in which case the pending IRQ3 interrupt request is deleted

(3) Bit 2—Interrupt Request 2 Flag (IRQ2F): Indicates that interrupt request 2 (IRQ2) has been input.

Bit 2

IRQ2F	Description
0	Interrupt request 2 (IRQ2) has not been input (Initial value)
1	Interrupt request 2 (IRQ2) has been input and is waiting for interrupt service (Clearing conditions) <ol style="list-style-type: none">1. Cleared automatically when the H8/500 CPU accepts IRQ2 and the interrupt vector is output2. Can also be cleared by reading 1, then writing 0, in which case the pending IRQ2 interrupt request is deleted

(4) Bit 1—Interrupt Request 1 Flag (IRQ1F): Indicates that interrupt request 1 (IRQ1) has been input.

Bit 1

IRQ1F	Description
0	Interrupt request 1 (IRQ1) has not been input (Initial value)
1	Interrupt request 1 (IRQ1) has been input and is waiting for interrupt service (Clearing conditions) <ol style="list-style-type: none">1. Cleared automatically when the H8/500 CPU accepts IRQ1 and the interrupt vector is output2. Can also be cleared by reading 1, then writing 0, in which case the pending IRQ1 interrupt request is deleted

(5) Bit 0—Reserved: Read-only bit, always read as 1.

5.2.4 Internal Interrupts

There are 39 internal interrupt sources in the on-chip supporting modules. A different interrupt vector address is assigned to each source, so the interrupt handling routine does not have to determine which interrupt has occurred.

Priority levels from 7 to 0 are assigned to each module in IPRA to IPRF. DTEA to DTEF indicate which interrupts in each module are served by the DTC.

When an internal interrupt request is accepted, the T bit in SR is cleared to 0 and the interrupt mask level in I_2 to I_0 is set to the value selected in IPRA to IPRF.

5.3 Register Descriptions

5.3.1 Interrupt Priority Registers A to F

The six interrupt priority registers (IPRA to IPRF) assign priority levels from 7 to 0 to interrupt sources other than NMI. A reset initializes IPRA to IPRF to H'00.

The bit structure of IPRA to IPRF is shown next.

Bit	7	6	5	4	3	2	1	0
	—				—			
Initial value	0	0	0	0	0	0	0	0
R/W	R	R/W	R/W	R/W	R	R/W	R/W	R/W
	Upper four bits				Lower four bits			

(1) Bits 7 to 4—Interrupt Priority, Upper Four Bits: These bits select an interrupt priority level. Bit 7 must always be cleared to 0.

(2) Bits 3 to 0—Interrupt Priority, Lower Four Bits: These bits select an interrupt priority level. Bit 3 must always be cleared to 0.

The on-chip supporting modules are mapped onto the interrupt priority registers as shown in table 5-4. Each interrupt priority register is assigned two on-chip supporting modules. The upper four bits of the interrupt priority register specify the priority level of one module; the lower four bits specify the priority of the other module.

Table 5-5 indicates how priority levels are set in the interrupt priority registers. For example, to assign level 7 to SCI1, set bits 6 to 4 in IPRF to 111.

Table 5-4 On-Chip Supporting Modules and Interrupt Priority Registers

	Bits 6 to 4	Bits 2 to 0
Register	On-Chip Supporting Module	On-Chip Supporting Module
IPRA	IRQ ₀ , WDT, A/D converter	IRQ ₁ to IRQ ₃
IPRB	IPU channel 1	IPU channel 1
IPRC	IPU channel 2	IPU channel 3
IPRD	IPU channel 4	IPU channel 5
IPRE	IPU channel 6	IPU channel 7
IPRF	SCI1	SCI2

Table 5-5 Interrupt Priority Settings in IPRH and IPRL

Setting of Bits 6 to 4 or Bits 2 to 0	Interrupt Priority Level
000	0
001	1
010	2
011	3
100	4
101	5
110	6
111	7

5.3.2 Timing of Priority Changes

The interrupt controller requires two system clock cycles (2 ϕ) to determine the priority level of an interrupt. When an instruction modifies an instruction priority register, the new priority takes effect starting from the third state after that instruction has been executed.

5.4 Interrupt Operations

Interrupt operations are described next.

5.4.1 Operations up to Interrupt Acceptance

Figure 5-2 is a flowchart of the interrupt sequence up to the point at which an interrupt is accepted.

1. The interrupt controller receives interrupt request signals from one or more on-chip supporting modules or external interrupt sources.
2. The interrupt controller checks the interrupt priorities assigned in IPRA to IPRF and selects the interrupt with the highest priority level. Interrupts with lower priorities remain pending. Among interrupts with the same assigned level, the interrupt controller determines priority as explained in table 5-3.
3. The interrupt controller compares the priority level of the selected interrupt request with the mask level in SR bits I_2 to I_0 . If the priority level is equal to or less than the mask level, the interrupt request remains pending. If the priority level is higher than the mask level, the interrupt controller accepts the interrupt request.
4. After accepting an interrupt, the interrupt controller checks the corresponding bit in DTEA to DTEF. If this bit is set to 1, the data transfer controller is started. If it is cleared to 0, interrupt exception handling is started.

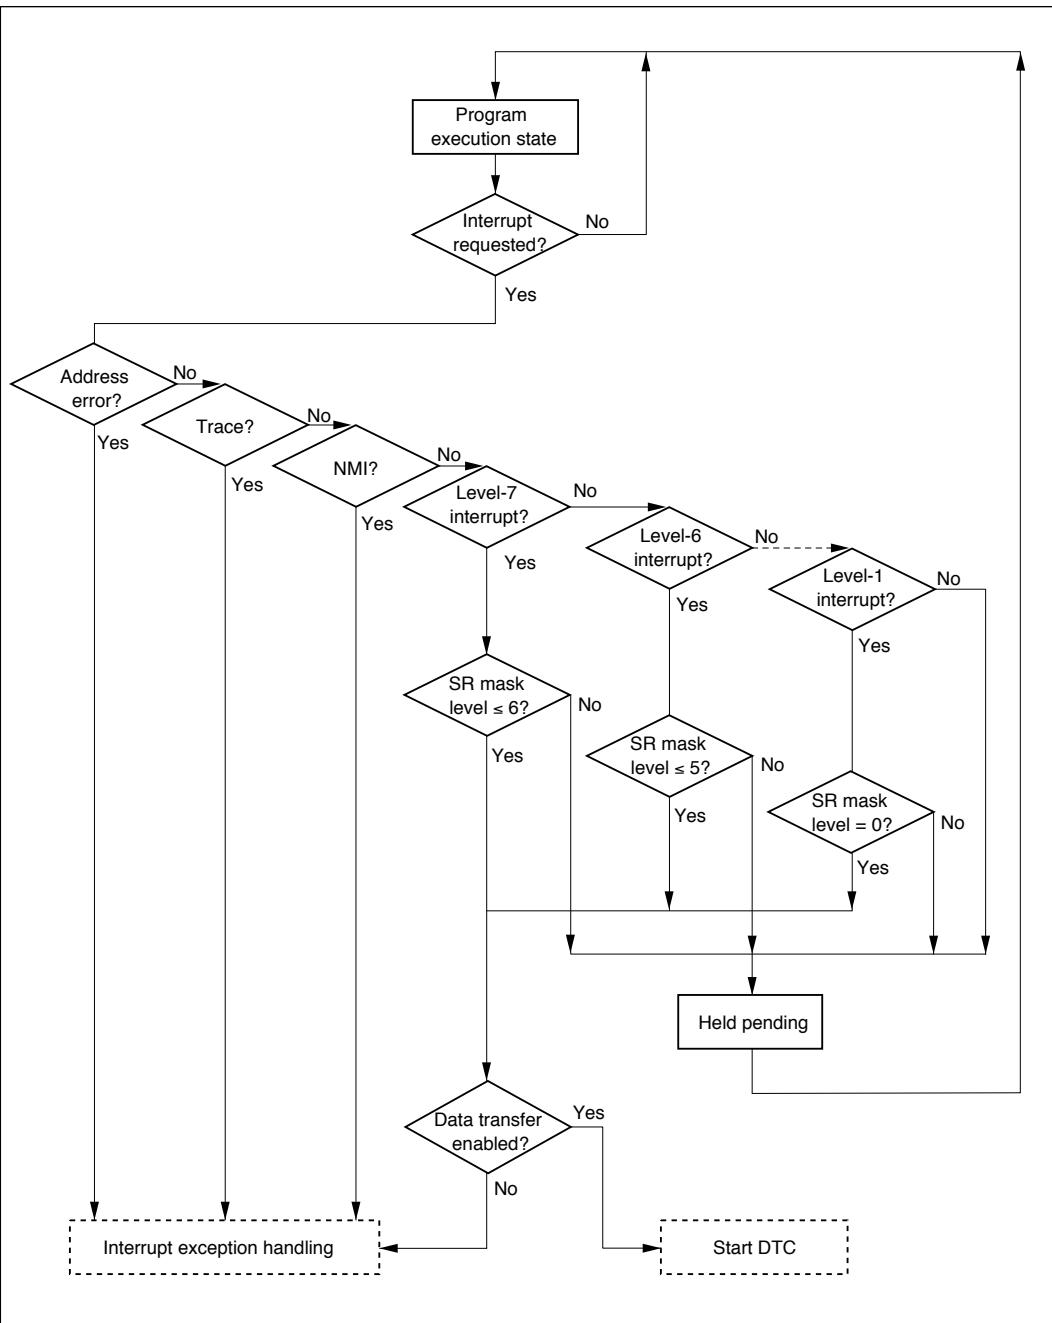

Figure 5-2 Flowchart up to Interrupt Acceptance

5.4.2 Interrupt Exception Handling

Interrupt exception handling is described below. Figure 5-3 shows a flowchart. For DTC operations, see section 6, “Data Transfer Controller.”

1. When the interrupt controller accepts an interrupt, after the H8/500 CPU finishes executing the current instruction, PC and SR (in minimum mode) or PC, CP, and SR (in maximum mode) are pushed on the stack, leaving the stack in the condition shown in section 5.4.4, “Stack after Interrupt Exception Handling.”
2. The interrupt controller clears the T bit in SR to 0, and sets the interrupt mask level (I_2 to I_0) to the priority level of the interrupt.
3. In minimum mode, the interrupt controller reads a one-word vector address corresponding to the accepted interrupt from the vector table and copies this word into PC. Execution of the interrupt handling routine then starts from the PC address. In maximum mode, the interrupt controller reads a two-word vector address corresponding to the accepted interrupt from the vector table, copies the lower byte of the first word into CP, and copies the second word into PC. Execution of the interrupt handling routine then starts from the address indicated by CP and PC.

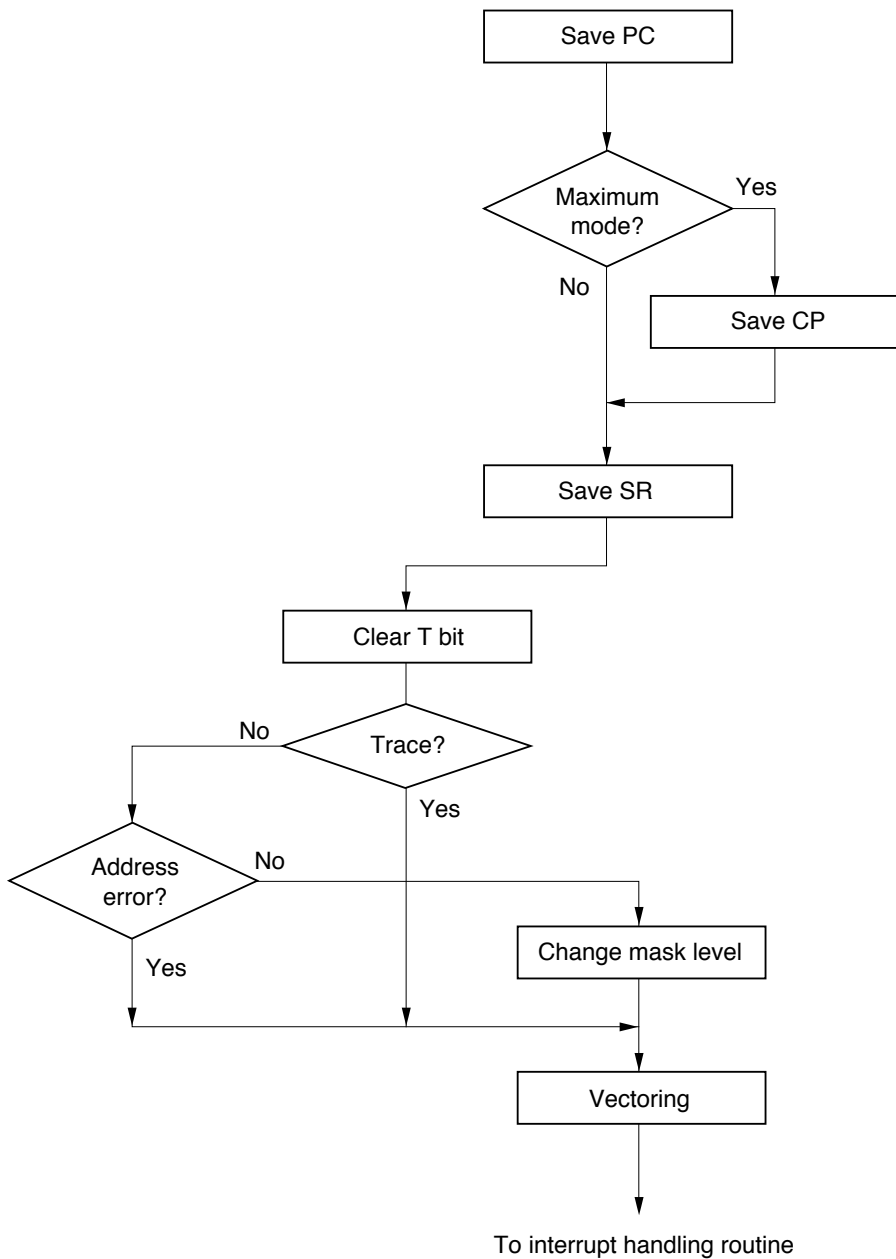

Figure 5-3 Interrupt Exception Handling Flowchart

5.4.3 Interrupt Exception Handling Sequence

Figure 5-4 is a timing diagram of the interrupt sequence in minimum mode, for the case in which the interrupt handling routine starts at an even address and the program area and stack area are in the external 16-bit-bus two-state-access address space.

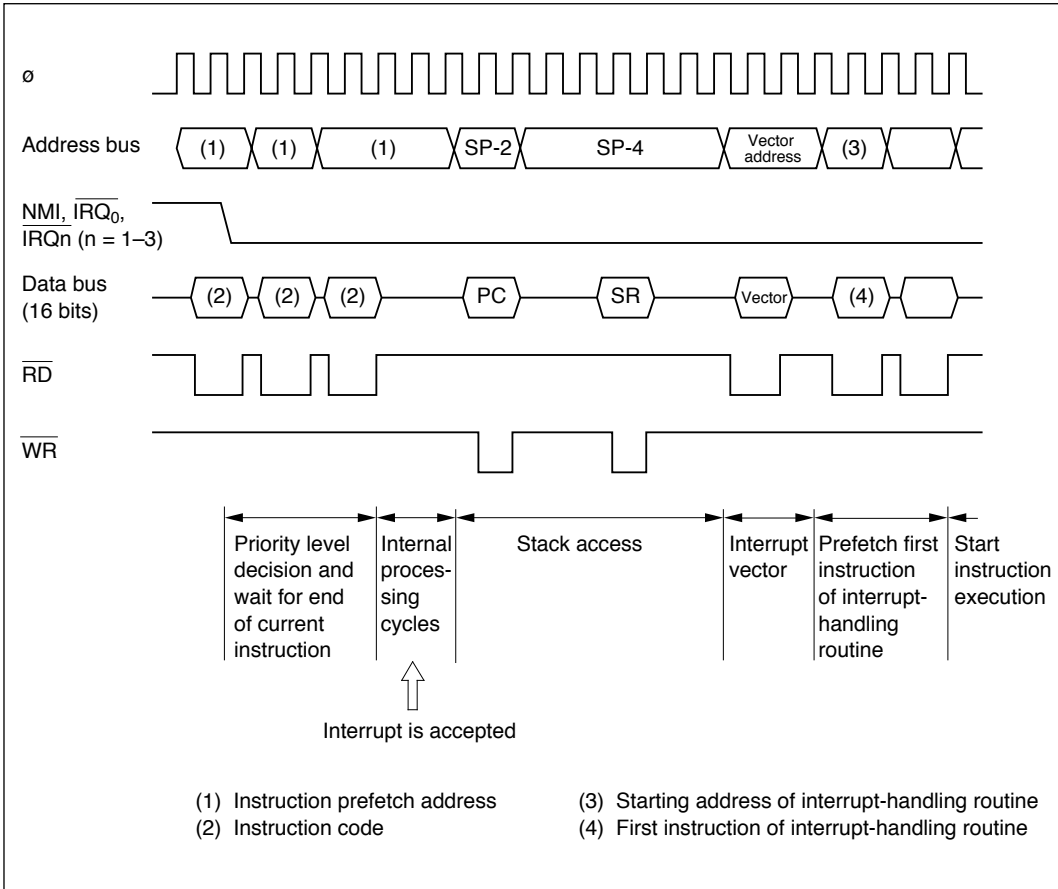

Figure 5-4 Interrupt Sequence in Minimum Mode

Figure 5-5 is a timing diagram of the interrupt sequence in maximum mode, for the case in which the interrupt handling routine starts at an even address and the program area and stack area are in the external 16-bit-bus two-state-access address space.

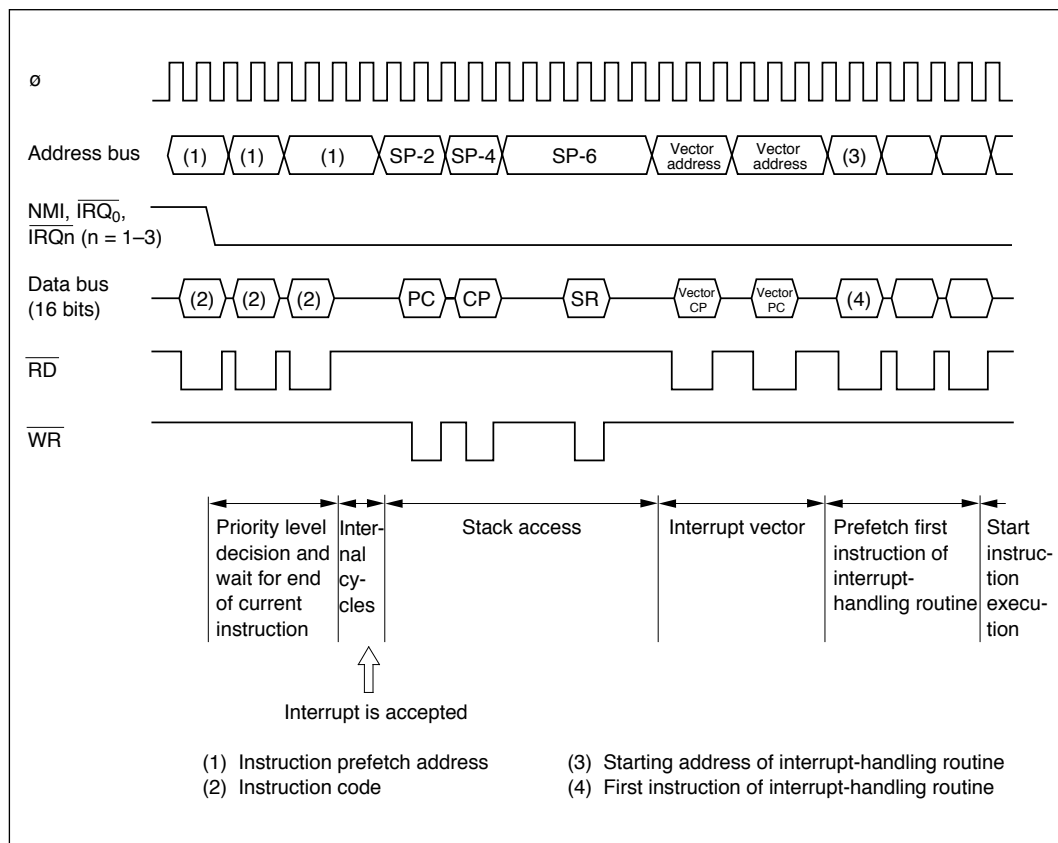

Figure 5-5 Interrupt Sequence in Maximum Mode

5.4.4 Stack after Interrupt Exception Handling

Figure 5-6 shows the stack before and after interrupt exception handling in minimum mode. Figure 5-7 shows the stack before and after interrupt exception handling in maximum mode. The PC value saved on the stack is the address of the next instruction to be executed.

SP must always point to an even address. If an odd address is set in SP, an address error will occur when the stack is accessed.

Figure 5-6 Stack before and after Interrupt Exception Handling in Minimum Mode

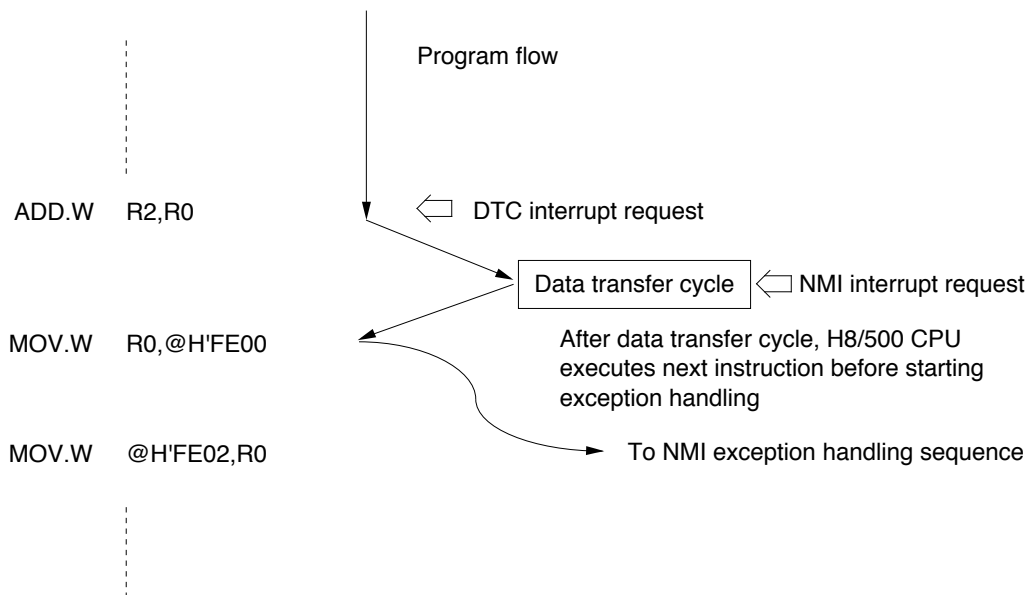

Figure 5-7 Stack before and after Interrupt Exception Handling in Maximum Mode

5.5 Interrupts during DTC Operation

If an interrupt is requested during a DTC data transfer cycle, the interrupt controller holds the interrupt pending until the data transfer cycle has been completed and the next instruction has been executed. An example is shown below.

Example:

5.6 Interrupt Response Time

The H8/538F can access a memory area in two states via a 16-bit bus. Fastest interrupt service is obtained by placing the program and stack in this area. Table 5-6 indicates the interrupt response time in minimum mode. The maximum number of states occurs when the LDM instruction is executed with all registers specified.

Table 5-6 Number of States before Interrupt Service in Minimum Mode

Reason for Wait	Number of States			
	Stack Area: 16* ¹		Stack Area: 8* ²	
	Instruction: 16* ³	Instruction: 8* ⁴	Instruction: 16* ³	Instruction: 8* ⁴
Interrupt priority decision and comparison with SR mask level	2	2	2	2
Maximum number of states to completion of current instruction	38	—	38	—
	—	74 + 16 m	—	74 + 16 m
Saving of PC and SR	16	16	—	—
	—	—	28 + 6 m	28 + 6 m
Total number of states	56	92 + 16 m	68 + 6 m	104 + 22 m

Notes: 1. Stack area in 16-bit-bus two-state-access address space
 2. Stack area in 8-bit-bus three-state-access address space
 3. Instruction in 16-bit-bus two-state-access address space
 4. Instruction in 8-bit-bus three-state-access address space
 m: Number of wait states inserted in memory access

Table 5-7 indicates the interrupt response time in maximum mode. The maximum number of states occurs when the LDM instruction is executed with all registers specified.

Table 5-7 Number of States before Interrupt Service in Maximum Mode

Reason for Wait	Number of States			
	Stack Area: 16* ¹		Stack Area: 8* ²	
	Instruction: 16* ³	Instruction: 8* ⁴	Instruction: 16* ³	Instruction: 8* ⁴
Interrupt priority decision and comparison with SR mask level	2	2	2	2
Maximum number of states to completion of current instruction	38	74 + 16 m	38	74 + 16 m
Saving of PC, CP, and SR	21	21	41 + 10 m	41 + 10 m
Total number of states	61	97 + 16 m	81 + 10 m	117 + 26 m

Notes: 1. Stack area in 16-bit-bus two-state-access address space
2. Stack area in 8-bit-bus three-state-access address space
3. Instruction in 16-bit-bus two-state-access address space
4. Instruction in 8-bit-bus three-state-access address space
m: Number of wait states inserted in memory access

Section 6 Data Transfer Controller

6.1 Overview

The H8/538F includes an interrupt-triggered data transfer controller (DTC). The DTC can transfer data between memory and I/O, memory and memory, or I/O and I/O without using the CPU. For example, the DTC can set data in the registers of an on-chip supporting module or send data to an I/O port or serial communication interface (SCI) independently of program execution. The H8/500 CPU halts while the DTC is operating.

6.1.1 Features

The features of the DTC are:

- The source address and destination address can be set anywhere in the 64-kbyte address space of page 0.
- The DTC can be programmed to increment the source address and/or destination address after each byte or word is transferred.
- The DTC can be programmed to transfer one byte or one word of data per interrupt.
- A data transfer count of up to 65,536 bytes or words can be set in the data transfer counter register (DTCR).
- After a data transfer, if the data transfer count is zero, the interrupt request that started the DTC is transferred to the H8/500 CPU. The H8/500 CPU then starts normal interrupt exception handling.

6.1.2 Block Diagram

Figure 6-1 shows a block diagram of the data transfer controller.

When DTC service is requested, the DTC loads its control registers from memory with information corresponding to the interrupt source, transfers a byte or word of data, and writes any altered register information back to memory.

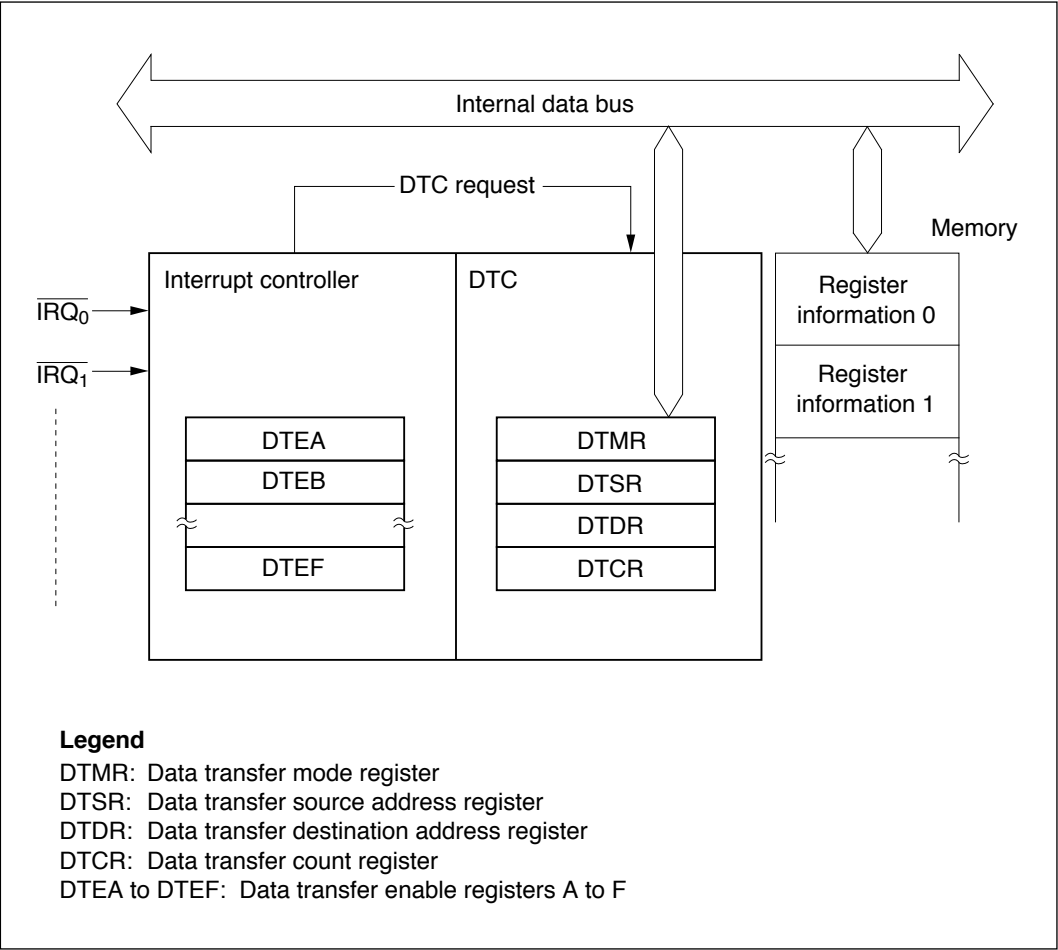

Figure 6-1 Block Diagram of Data Transfer Controller

6.1.3 Register Configuration

Table 6-1 summarizes the DTC control registers.

Table 6-1 DTC Registers

Name	Abbreviation	R/W
Data transfer mode register	DTMR	—
Data transfer source address register	DTSR	—
Data transfer destination address register	DTDR	—
Data transfer count register	DTCR	—

These registers cannot be accessed directly. To set information in the DTC control registers, software should alter the information on memory.

Starting of the DTC is controlled by the interrupt controller's data transfer enable registers.

Table 6-2 summarizes these registers.

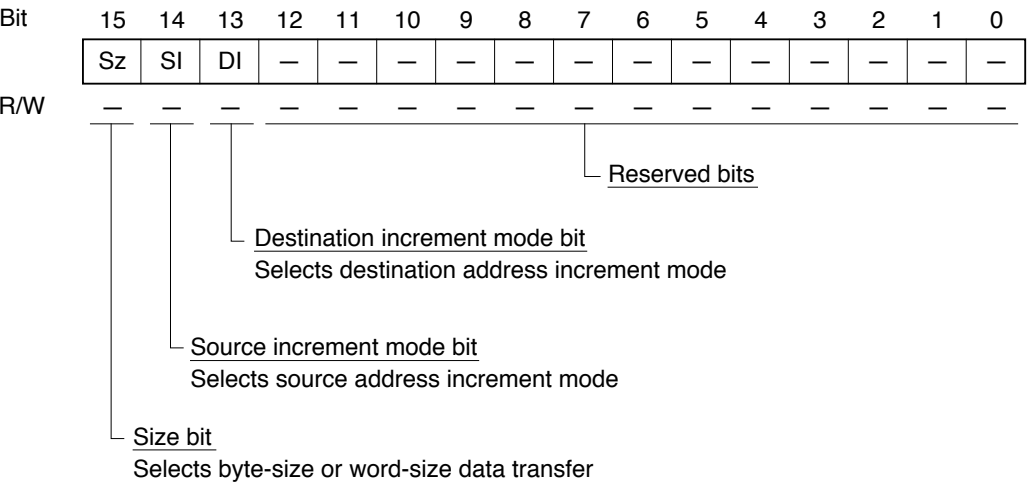

Table 6-2 Data Transfer Enable Registers

Address	Name	Abbreviation	R/W	Initial Value
H'FF08	Data transfer enable register A	DTEA	R/W	H'00
H'FF09	Data transfer enable register B	DTEB	R/W	H'00
H'FF0A	Data transfer enable register C	DTEC	R/W	H'00
H'FF0B	Data transfer enable register D	DTED	R/W	H'00
H'FF0C	Data transfer enable register E	DTEE	R/W	H'00
H'FF0D	Data transfer enable register F	DTEF	R/W	H'00

6.2 Register Descriptions

6.2.1 Data Transfer Mode Register

The data transfer mode register (DTMR) is a 16-bit register that selects the data size and specifies whether to increment the source and destination addresses. The DTMR bit structure is shown next.

(1) **Bit 15—Size (Sz):** Selects byte-size or word-size data transfer.

Bit 15	
Sz	Description
0	Byte transfer
1	Word (two-byte) transfer*

Note: * For word transfer, DTSR and DTDR must indicate even addresses.

(2) **Bit 14—Source Increment Mode (SI):** Specifies whether to increment the source address.

Bit 14	
SI	Description
0	Not incremented
1	1. If Sz = 0: incremented by +1 after each data transfer 2. If Sz = 1: incremented by +2 after each data transfer

(3) Bit 13—Destination Increment Mode (DI): Specifies whether to increment the destination address.

Bit 13

DI	Description
0	Not incremented
1	1. If Sz = 0: incremented by +1 after each data transfer 2. If Sz = 1: incremented by +2 after each data transfer

(4) Bits 12 to 0—Reserved: Reserved bits.

6.2.2 Data Transfer Source Address Register

The data transfer source address register (DTSR) is a 16-bit register that designates the data transfer source address. The DTSR bit structure is shown next.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R/W	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

For word transfer the source address must be even. In maximum mode, the source address is implicitly located in page 0.

6.2.3 Data Transfer Destination Address Register

The data transfer destination address register (DTDR) is a 16-bit register that designates the data transfer destination address. The DTDR bit structure is shown next.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R/W	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

For word transfer the destination address must be even. In maximum mode, the destination address is implicitly located in page 0.

6.2.4 Data Transfer Count Register

The data transfer count register (DTCR) is a 16-bit register that designates the number of bytes or words to be transferred. The initial count can be set from 1 to 65,536. A register value of 0 designates an initial count of 65,536. The DTCR bit structure is shown next.

The data transfer count register is decremented automatically after each byte or word is transferred. When the count reaches 0, indicating that the designated number of bytes or words have been transferred, the DTC sends the H8/500 CPU an interrupt request with the same interrupt source that started the data transfer.

6.2.5 Data Transfer Enable Registers A to F

The six data transfer enable registers (DTEA to DTEF) specify whether an interrupt starts the DTC. (Certain interrupts, such as NMI, cannot start the DTC.) The bit structure of DTEA to DTEF is shown next.

The bits in these registers are assigned to interrupts as indicated in table 6-3.

If the bit for a certain interrupt is set to 1, that interrupt is regarded as a request for DTC service. If the bit is cleared to 0, the interrupt is regarded as an H8/500 CPU interrupt request.

Only the interrupts indicated in table 6-3 can request DTC service in the H8/538F. DTE bits not assigned to any interrupt (indicated by “—” in table 6-3) should be left cleared to 0.

Table 6-3 Bit Assignments of Data Transfer Enable Registers

Register	On-Chip Supporting Module	Bits 7 to 4				On-Chip Supporting Module	Bits 3 to 0			
		7	6	5	4		3	2	1	0
DTEA	IRQ ₀ , ADI	—	ADI	(IRQ0)	IRQ0	IRQ ₁₋₃	—	IRQ3	IRQ2	IRQ1
DTEB	IPU (CH1)	—	CMI1,2	IMI2	IMI1	IPU (CH1)	—	CMI3,4	IMI4	IMI3
DTEC	IPU (CH2)	—	CMI1,2	IMI2	IMI1	IPU (CH3)	—	CMI1,2	IMI2	IMI1
DTED	IPU (CH4)	—	CMI1,2	IMI2	IMI1	IPU (CH5)	—	CMI1,2	IMI2	IMI1
DTEE	IPU (CH6)	—	—	IMI2	IMI1	IPU (CH7)	—	—	IMI2	IMI1
DTEF	SCI1	—	TI	RI	—	SCI2	—	TI	RI	—

6.2.6 Note on Timing of DTE Modifications

The interrupt controller requires two system clock cycles (2ϕ) to determine the priority level of an interrupt. When an instruction modifies one of DTEA to DTEF, the new setting takes effect starting from the third state after the instruction has been executed.

6.3 Operation

DTC operations are described next.

6.3.1 DTC Operations

Figure 6-2 is a flowchart of the data transfer operations performed by the DTC. For operations from the occurrence of an interrupt until the DTC is activated, see section 5.4.1, “Sequence of Interrupt Operations.”

1. From the DTC vector table, the DTC reads the address at which the register information for the interrupt is stored in memory and loads the stored information into its control registers.

When the DTC is activated, the interrupt source that activated the DTC is cleared, except for interrupts from the serial communication interface.

2. The DTC transfers the data and increments the source and destination addresses as required, then decrements DTCCR.

If the DTC was activated by an interrupt from the serial communication interface, the interrupt source is cleared when the DTC accesses the transmit data register (TDR) or receive data register (RDR).

3. The DTC writes updated register information back to memory.
4. If the DTCCR value is 0, the H8/500 CPU starts interrupt exception handling for the interrupt that activated the DTC.

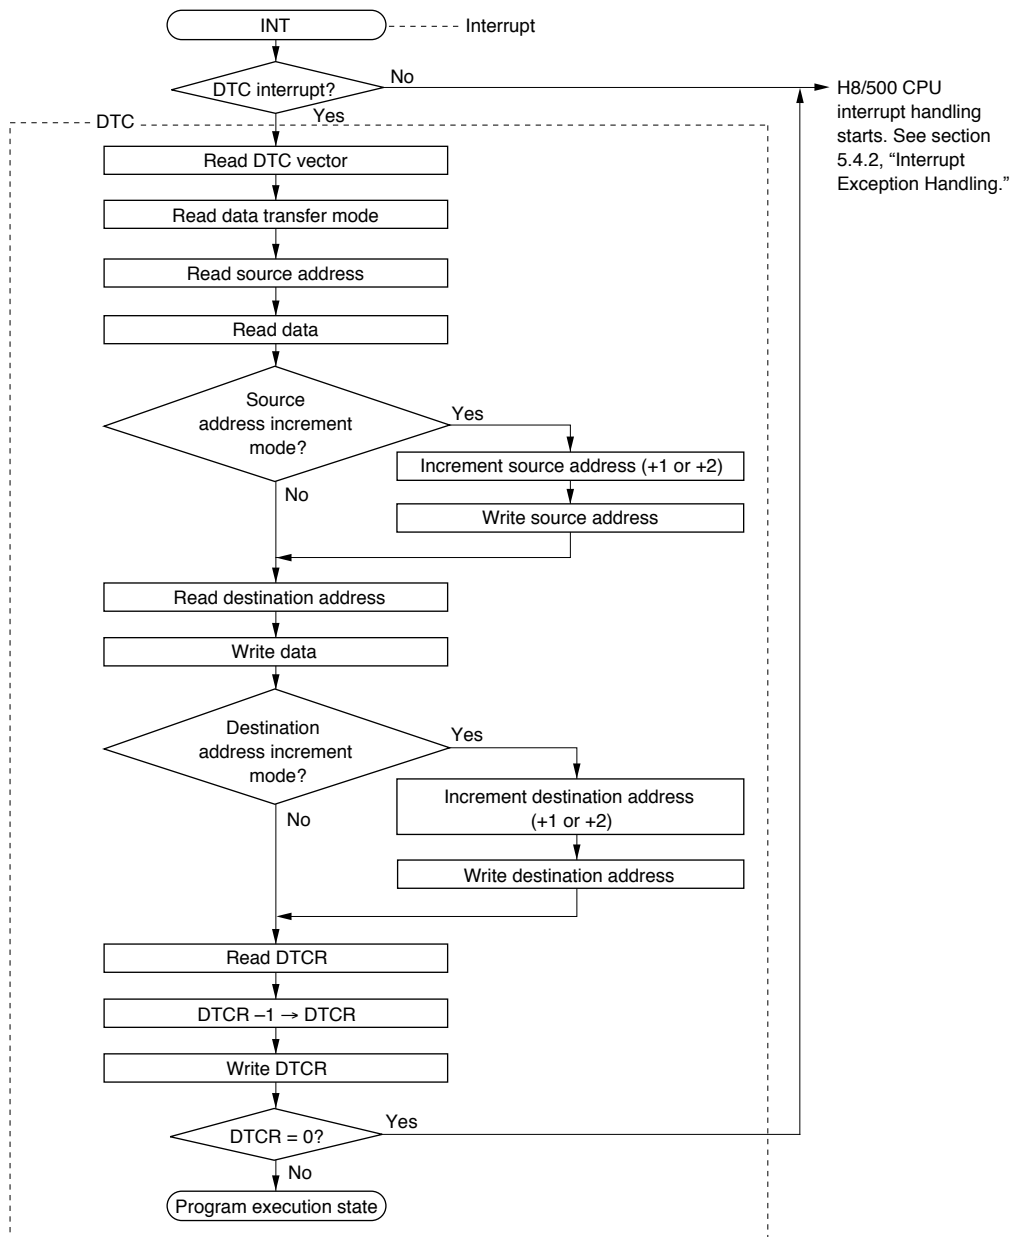

Figure 6-2 Flowchart of DTC Operations

6.3.2 DTC Vector Table

Figure 6-3 shows how the DTC vector table works.

For each interrupt that can request DTC service, the DTC vector table provides a pointer to an address in memory where the DTC control register information for that interrupt is stored. Register information tables can be placed in any available locations in page 0.

Figure 6-3 shows an example in which the register information is located on RAM. Register information can also be stored on ROM if there is no need to update the information after each transfer (if the source and destination addresses are not incremented and the desired data transfer count is one).

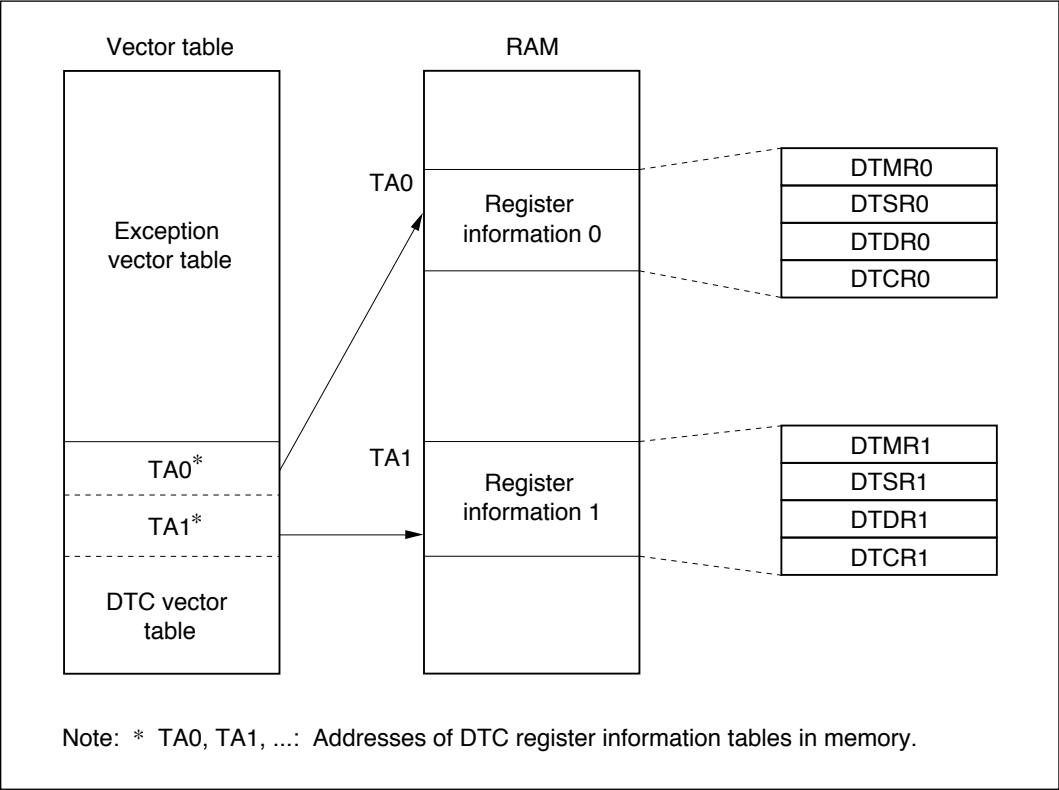

Figure 6-3 DTC Vector Table

The DTC vector table structure differs between minimum and maximum modes. In maximum mode there is no page specification: page 0 is assumed implicitly.

Figure 6-4 shows a DTC vector table entry in minimum and maximum mode.

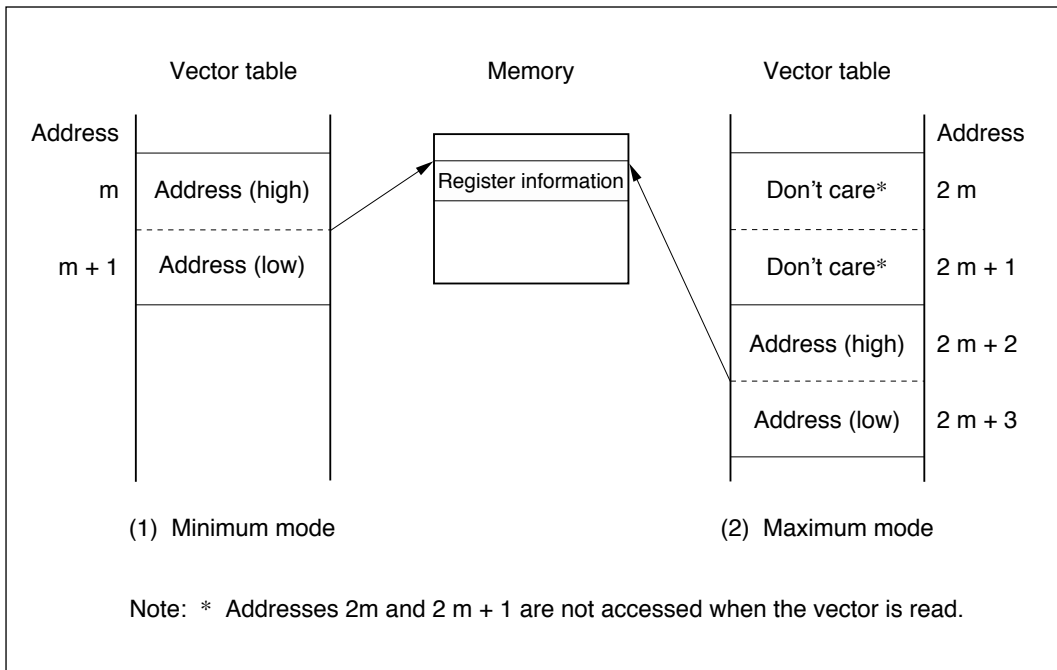

Figure 6-4 DTC Vector Table Entry

Table 6-4 lists the address of the entry in the DTC vector table for each interrupt.

Table 6-4 Addresses of DTC Vectors

Interrupt Source		Address of Vector Table Entry	
		Minimum Mode	Maximum Mode

6.3.3 Location of Register Information in Memory

For each interrupt, the DTC control register information is stored in four consecutive words in memory in the order shown in figure 6-5.

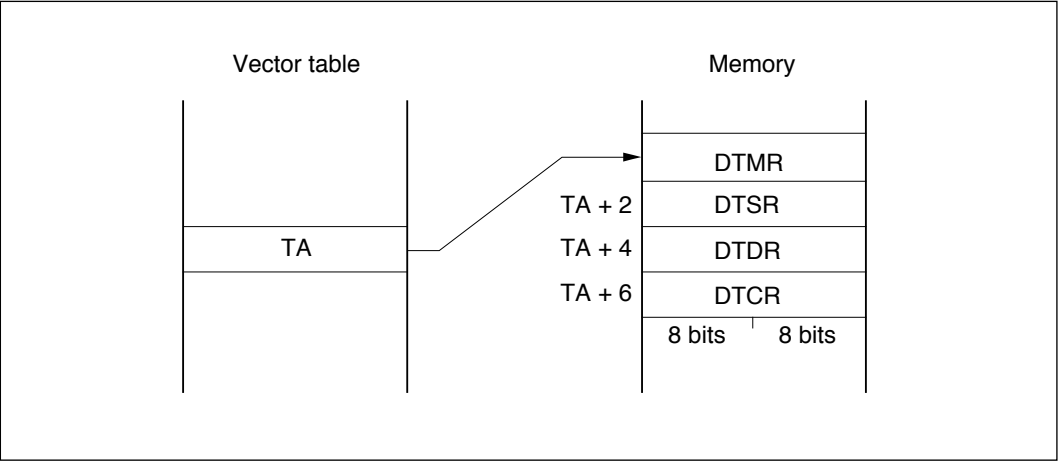

Figure 6-5 Order of Register Information

6.3.4 Number of States per Data Transfer

Table 6-5 lists the number of states required per data transfer, assuming that the DTC control register information is stored in the 16-bit-bus two-state-access address space.

Table 6-5 Number of States per Data Transfer

Increment Mode		16-Bit-Bus 2-State-Access Address Space	On-Chip Supporting Module	8-Bit-Bus 3-State-Access Address Space	On-Chip Supporting Module
Source (SI)	Destination (DI)	Byte Transfer	Word Transfer	Byte Transfer	Word Transfer
0	0	31	34	32	38
0	1	33	36	34	40
1	0	33	36	34	40
1	1	35	38	36	42

Note: Numbers in the table are the number of states.

The values in table 6-5 are calculated from the formula:

$$N = 26 + 2 \times SI + 2 \times DI + M_S + M_D$$

Where M_S and M_D have the following meanings:

M_S : Number of states for reading source data

M_D : Number of states for writing destination data

The values of M_S and M_D depend on the data location as follows:

1. Byte or word data in 16-bit-bus two-state-access address space: 2 states
2. Byte data in eight-bit-bus three-state-access address space or on-chip supporting module: 3 states
3. Word data in eight-bit-bus three-state-access address space or on-chip supporting module: 6 states

If the DTC control register information is stored in the eight-bit-bus three-state-access address space, $20 + 4 \times SI + 4 \times DI$ must be added to the values in table 6-5.

Table 6-6 indicates the number of additional states between the occurrence of an interrupt request and the starting of the DTC (states during which the interrupt controller checks priority and waits for execution of the current instruction to end). At maximum, this number of states is the sum of the values indicated for items No. 1 and 2 in table 6-6.

If the data transfer count is 0 at the end of a data transfer cycle, the number of states from the end of the data transfer cycle until the first instruction of the interrupt-handling routine is executed is the value given for item No. 3 in table 6-6. The maximum number of states in table 6-6 occurs when the LDM instruction is executed with all registers specified.

Table 6-6 Number of States before Interrupt Service

No.	Reason for Wait	Number of States	
		Minimum Mode	Maximum Mode
1	Interrupt priority decision and comparison with mask level in SR	2	
2	Number of states to completion of current instruction	Instruction is in 16-bit-bus two-state-access address space (LDM instruction specifying all registers) 38	
		Instruction is in 8-bit-bus three-state-access address space (LDM instruction specifying all registers) 74 + 16 m	
3	Number of states from saving of PC and SR or PC, CP, and SR until prefetching of first instruction of interrupt-handling routine	Instruction is in 16-bit-bus two-state-access address space 16	21
		Instruction is in 8-bit-bus three-state-access address space 28 + 6 m	41 + 10 m

Notation

m: Number of wait states inserted in external memory access

6.4 Procedure for Using DTC

The procedure for using the DTC is explained next. Figure 6-6 is a flowchart.

Procedure for Using the DTC

1. DTC register setup: Set the appropriate DTMR, DTSR, DTDR, and DTCR register information in the memory location indicated in the DTC vector table.
2. DTEn, IPRn (n = A to F), and SR setup: Set the data transfer enable bit of the pertinent interrupt to 1, and set the priority of the interrupt source (in the interrupt priority register) and the interrupt mask level (in the CPU status register) so that the interrupt can be accepted.
3. Interrupt enabling: Set the interrupt enable bit for the interrupt source in the control register of the on-chip supporting module (or IRQ control register).

Following these preparations, the DTC will be started each time the interrupt occurs.

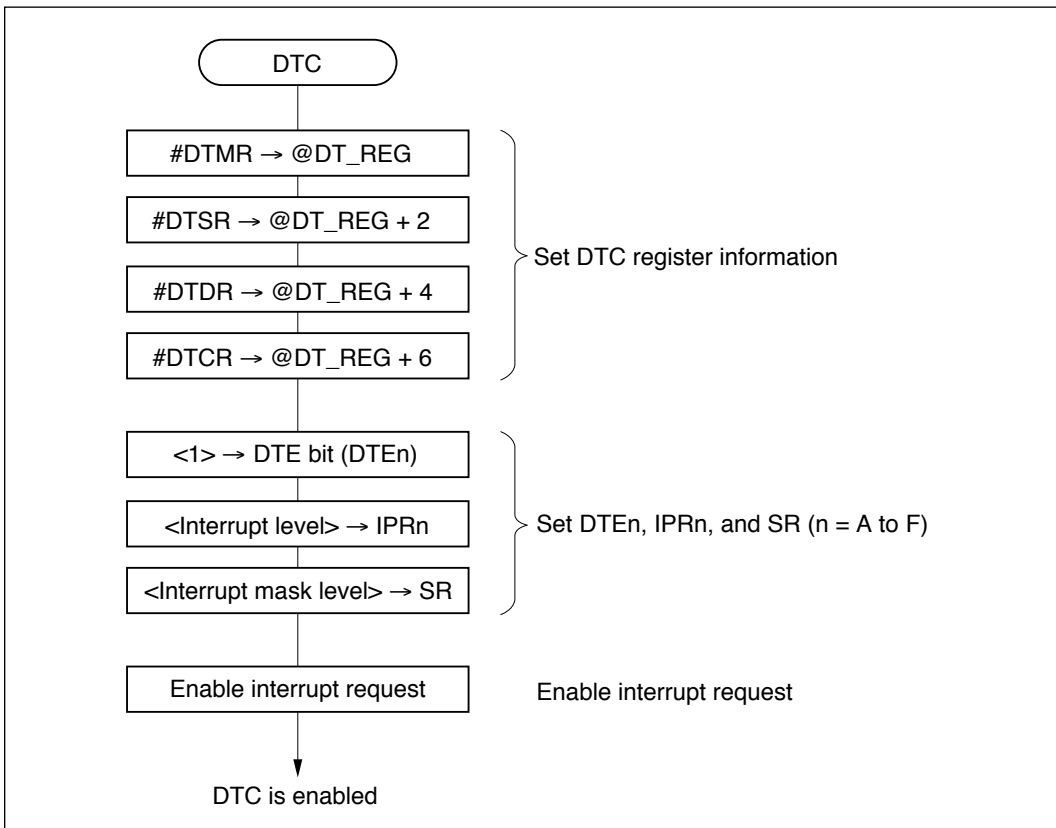

Figure 6-6 Procedure for Using DTC

6.5 Example

(1) **Purpose:** To receive 128 bytes of serial data via serial communication interface channel 1.

(2) **Conditions:**

- Operating mode: minimum mode.
- Received data are to be stored in consecutive addresses starting at H'FC00.
- The DTC vector table contains H'F6 at address H'00B2 and H'80 at address H'00B3.
- The desired interrupt mask level in the CPU status register is 4, and the desired SCI1 interrupt priority level is 5.

Table 6-7 shows the DTC control register information to set on RAM.

Table 6-7 DTC Control Register Information Set on RAM

Register	Setting	Value
DTMR	Byte transfer Source address fixed Destination address incremented	H'2000
DTSR	Address of SCI1 receive data register	H'FECD
DTDR	Address H'FC00	H'FC00
DTCR	Transfer count (128)	H'0080

(3) **Operation**

- ① Software sets DTMR, DTSR, DTDR, and DTCR information in RAM addresses H'F680 to H'F687 as shown in table 6-7.
- ② Software sets the RI (SCI1 Receive Interrupt) bit in data transfer enable register F (DTEF) to 1.
- ③ Software sets the interrupt mask level in SR bits I_2 to I_0 to 4, and the SCI1 interrupt priority level in the upper four bits of interrupt priority register F (IPRF) to 0101 (5).
- ④ Software sets SCI1 to the appropriate receive mode, and sets the receive interrupt enable bit (RIE) in the serial control register (SCR) to 1 to enable receive interrupts.
- ⑤ Thereafter, each time SCI1 receives one byte of data, the DTC is activated and transfers the byte of receive data into RAM. The DTC automatically clears the SCI1 receive interrupt request.

- ⑥ When 128 bytes have been transferred (DTCR = 0), SCI1 receive interrupt exception handling begins.
- ⑦ The interrupt-handling routine executes a receive wrap-up routine.

Figure 6-7 is a flowchart for this example.

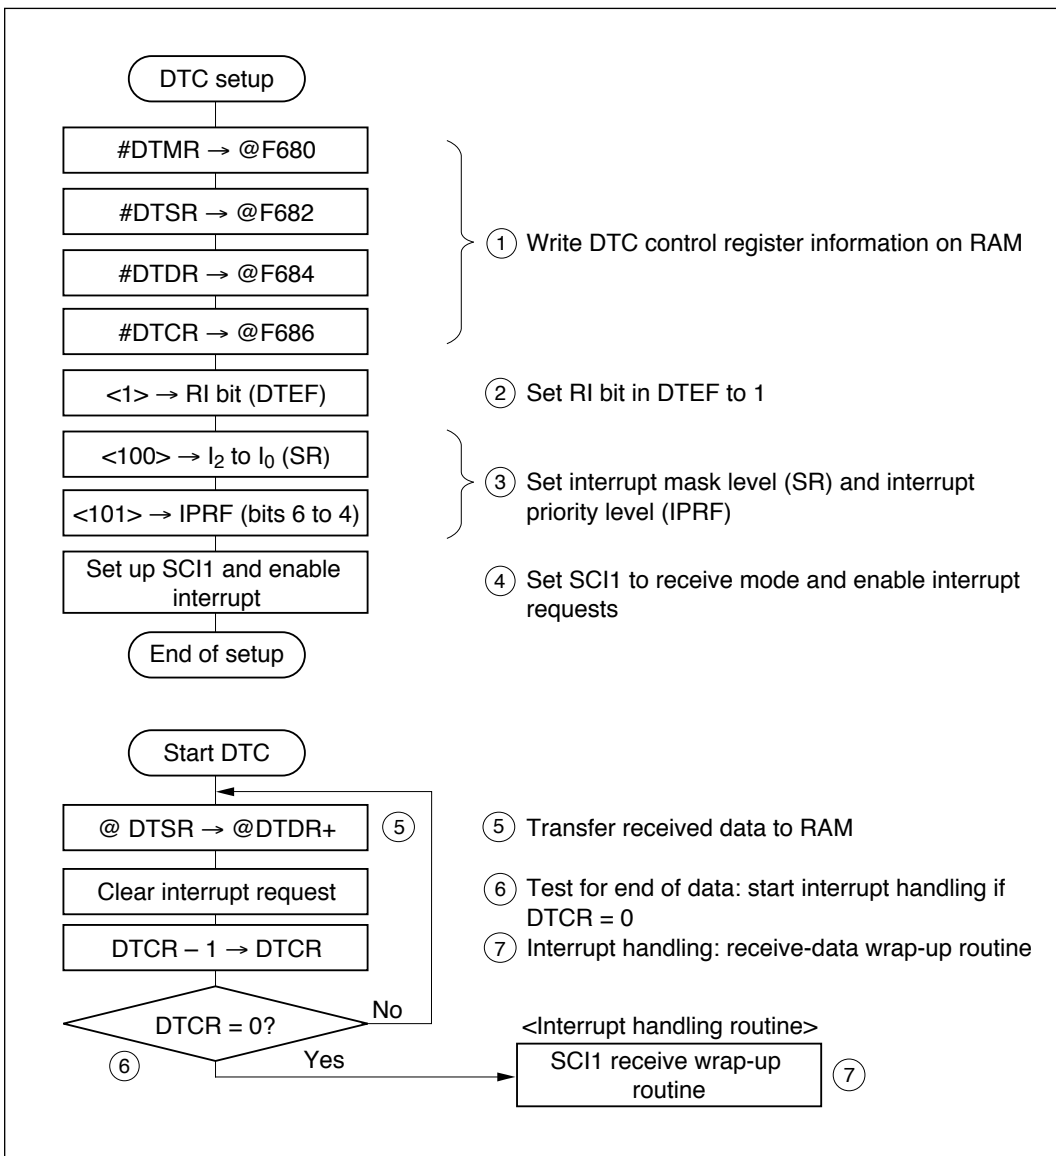

Figure 6-7 Flowchart for DTC Example

Figure 6-8 shows the DTC vector table and data in RAM for this example. Receive data are stored in consecutive addresses.

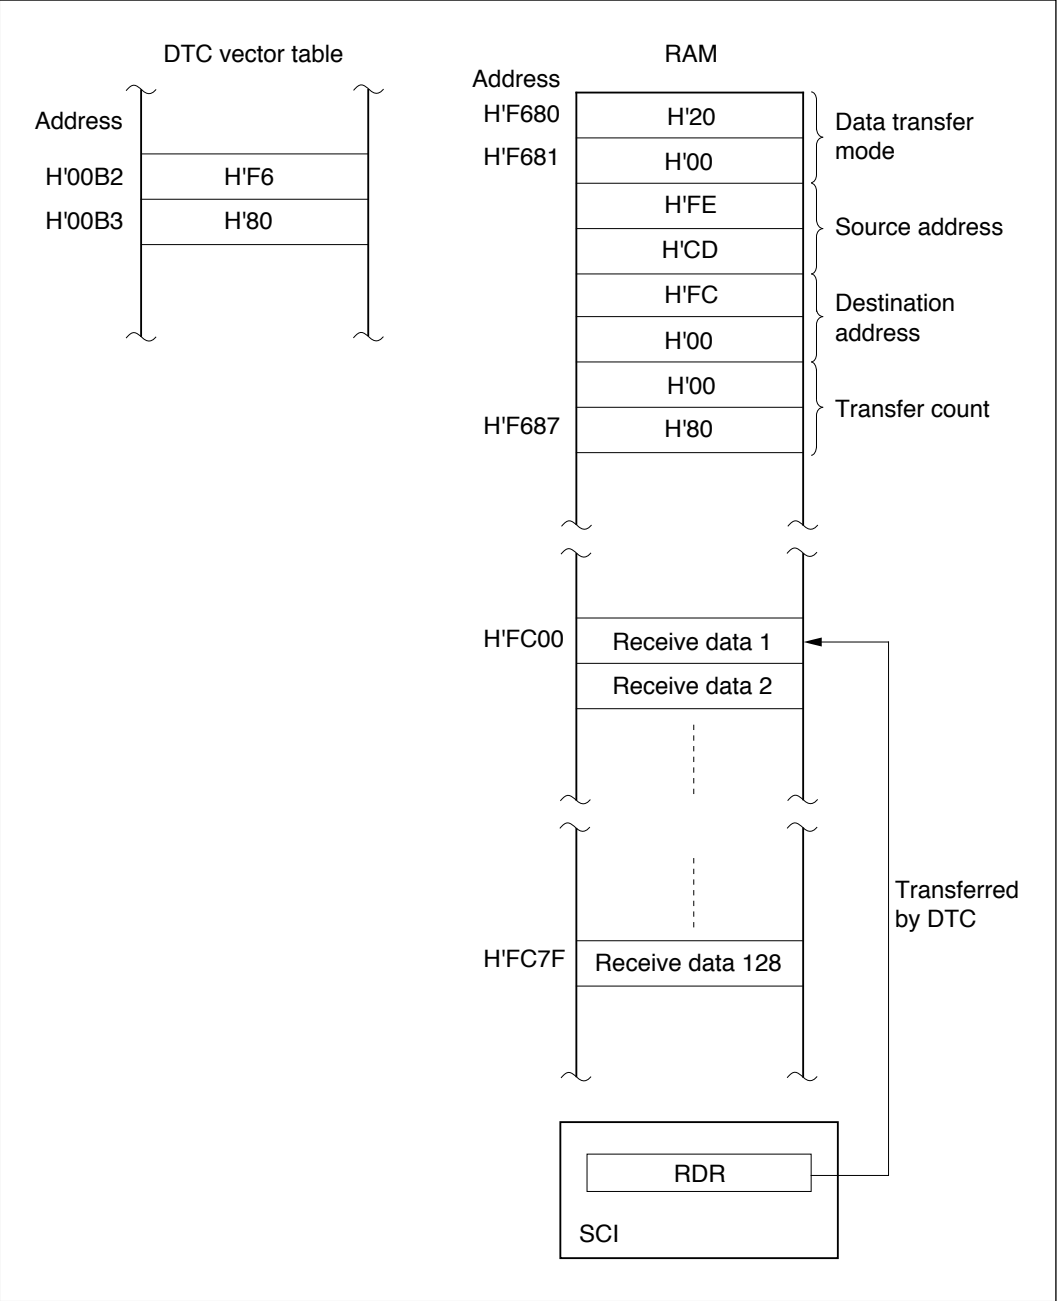

Figure 6-8 Example of Use of DTC to Receive Continuous Serial Data

Section 7 Wait-State Controller

7.1 Overview

For interfacing to low-speed external devices, the H8/538F has an on-chip wait-state controller (WSC) that can insert wait states (T_W) into bus cycles. The wait function can be used in CPU and DTC access cycles to the external three-state-access address space. It is not used in access to the two-state-access address space or the on-chip register area (H'FE80 to H'FFFF).

Wait states are inserted between the T_2 state and T_3 state in the bus cycle. The number of wait states can be selected by a value set in the wait control register (WCR), or by holding the $\overline{\text{WAIT}}$ pin low for the required interval.

7.1.1 Features

The features of the wait-state controller are:

- Selection of three operating modes

Programmable wait mode, pin wait mode, or pin auto-wait mode

- Selection of number of wait states

0, 1, 2, or 3 wait states can be inserted, and 4 or more wait states can be inserted in pin wait mode by holding the $\overline{\text{WAIT}}$ pin low.

7.1.2 Block Diagram

Figure 7-1 shows a block diagram of the wait-state controller.

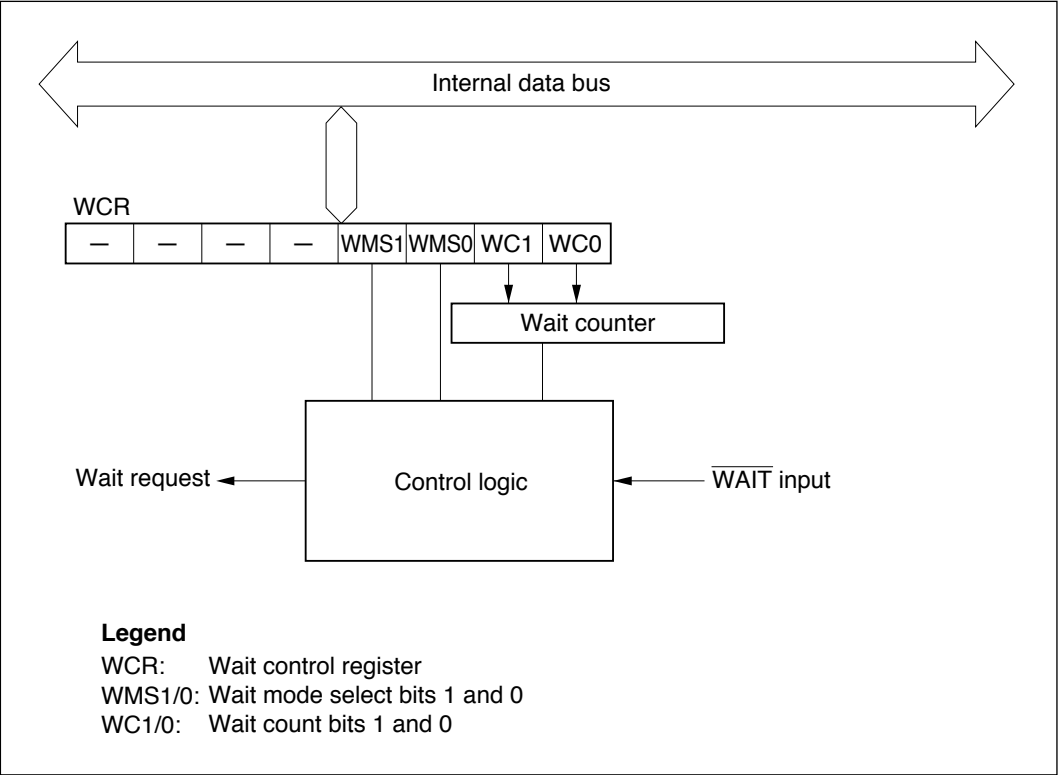

Figure 7-1 Block Diagram of Wait State Controller

7.1.3 Register Configuration

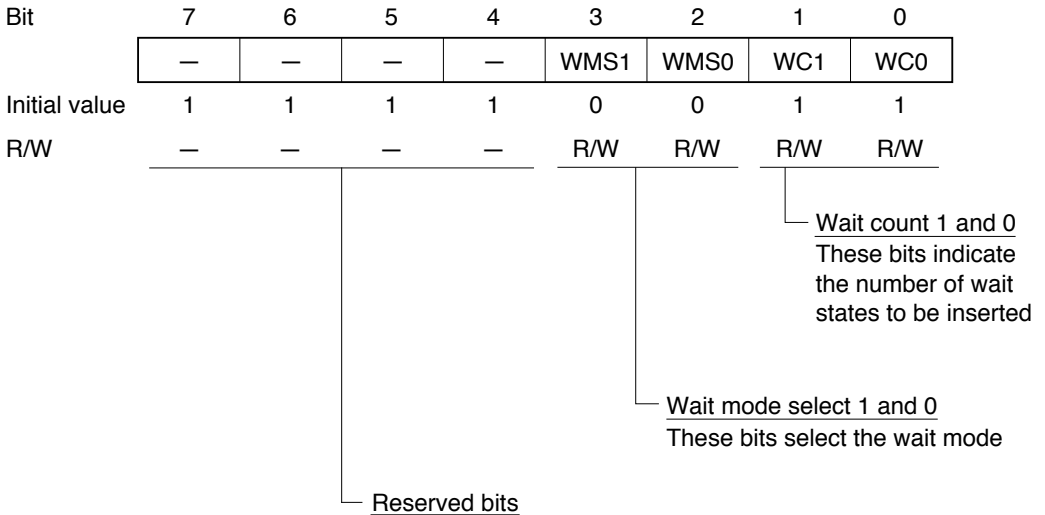

Table 7-1 summarizes the wait control register.

Table 7-1 Wait Control Register

Address	Name	Abbreviation	R/W	Initial Value
H'FF14	Wait control register	WCR	R/W	H'F3

7.2 Wait Control Register

The wait control register (WCR) is an eight-bit register that specifies the wait mode and the number of wait states to be inserted. The WCR bit structure is shown next.

WCR is initialized to H'A3 by a reset and in hardware standby mode. WCR is not initialized in software standby mode.

(1) **Bits 7 to 4—Reserved:** Read-only bits, always read as 1.

(2) **Bits 3 and 2—Wait Mode Select 1 and 0 (WMS1 and WMS0):** These bits select the wait mode.

Bit 3	Bit 2	Description
WMS1	WMS0	
0	0	Programmable wait mode (Initial value)
0	1	No wait states inserted, regardless of wait count
1	0	Pin wait mode
1	1	Pin auto-wait mode

(3) Bits 1 and 0—Wait Count 1 and 0 (WC1 and WC0): These bits specify the number of wait states to be inserted. Wait states (T_W) are inserted only in bus cycles in which the CPU or DTC accesses the external three-state-access address space.

Bit 1	Bit 0	
WC1	WC0	Description
0	0	No wait states inserted, except in pin wait mode
0	1	1 wait state inserted
1	0	2 wait states inserted
1	1	3 wait states inserted (Initial value)

7.3 Operation

Table 7-2 summarizes the operation of the three wait modes.

Table 7-2 Wait Modes

Mode	Description		
	$\overline{\text{WAIT}}$ Pin Function	Insertion Conditions	Number of Wait States Inserted
Programmable wait mode WMS1 = 0 WMS0 = 0	Disabled	Inserted in access to external three-state-access address space	0 to 3 states are inserted as specified by bits WC0 and WC1
Pin wait mode WMS1 = 1 WMS0 = 0	Enabled	Inserted in access to external three-state-access address space	<ul style="list-style-type: none"> 0 to 3 states are inserted as specified by bits WC0 and WC1 Additional states can be inserted by driving the $\overline{\text{WAIT}}$ signal low
Pin auto-wait mode WMS1 = 1 WMS0 = 1	Enabled	Inserted in access to external three-state-access address space if $\overline{\text{WAIT}}$ is low	0 to 3 states are inserted as specified by bits WC0 and WC1

7.3.1 Programmable Wait Mode

Programmable wait mode is selected when $WMS1 = 0$ and $WMS0 = 0$.

Whenever the CPU or DTC accesses the external three-state-access address space, the number of wait states selected by bits $WC1$ and $WC0$ are inserted. The PA_4/\overline{WAIT} pin is not used for wait control; it is available for general-purpose input or output.

Figure 7-2 shows the timing of operation in this mode when the wait count is 1 ($WC1 = 0$, $WC0 = 1$).

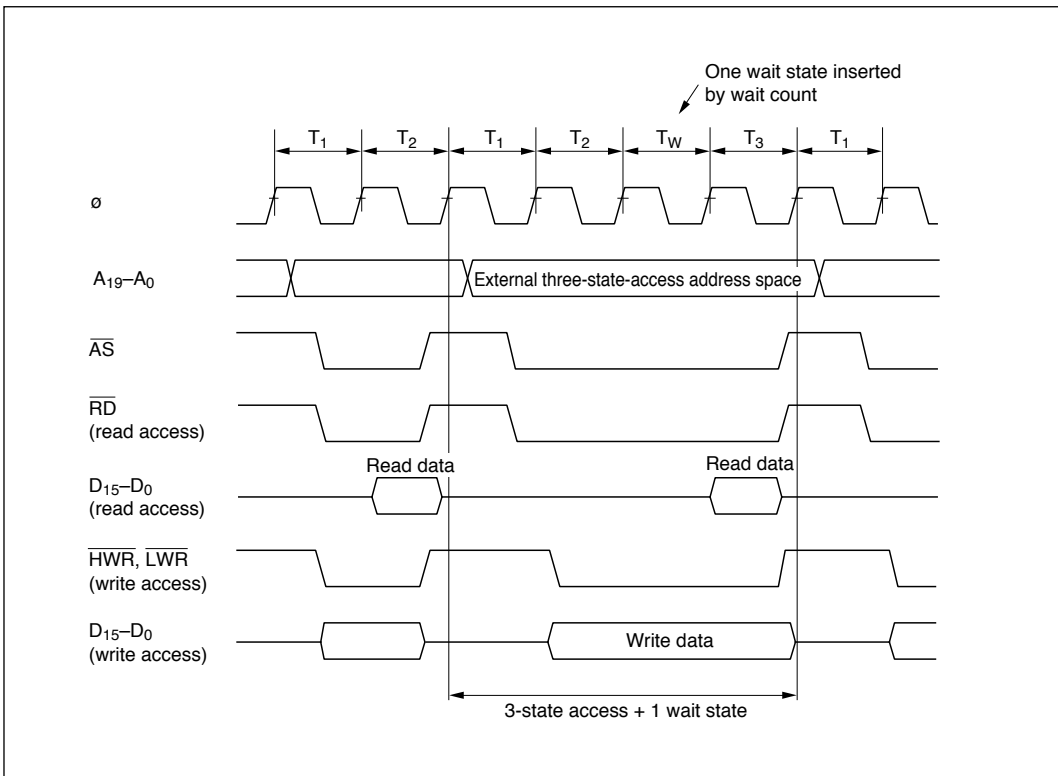

Figure 7-2 Programmable Wait Mode
(Example of External 16-Bit-Bus, Three-State-Access Address Space)

7.3.2 Pin Wait Mode

Pin wait mode is selected when $WMS1 = 1$ and $WMS0 = 0$. In this mode the \overline{WAIT} function of the PA_4/\overline{WAIT} pin is used automatically.

The number of wait states indicated by wait count bits $WC1$ and $WC0$ are inserted into any bus cycle in which the CPU or DTC accesses the external three-state-access address space. In addition, wait states are inserted if the \overline{WAIT} signal is driven low, even if the wait count is 0. Wait states continue to be inserted until the \overline{WAIT} signal goes high.

This mode is useful for inserting four or more wait states, or when different external devices require different numbers of wait states.

Figure 7-3 shows the timing of operation in this mode when the wait count is 1 ($WC1 = 0$, $WC0 = 1$) and the \overline{WAIT} signal is held low to insert one additional wait state.

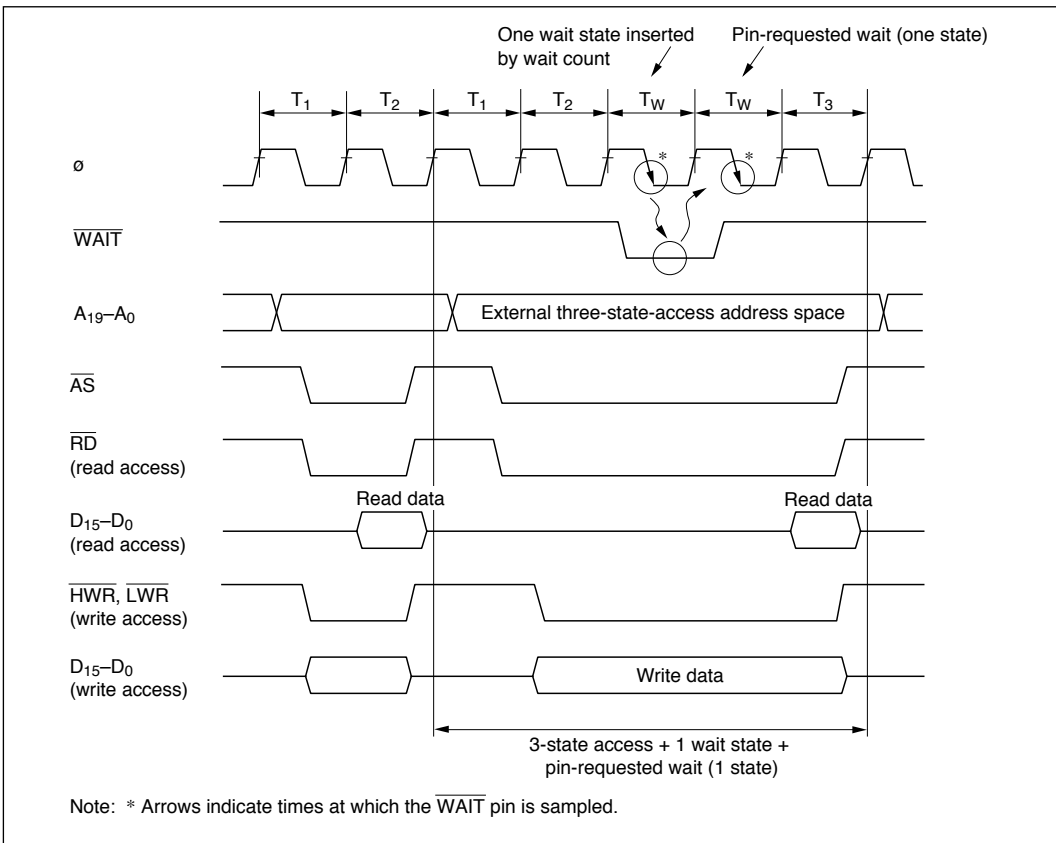

Figure 7-3 Pin Wait Mode
(Example of External 16-Bit-Bus, Three-State-Access Address Space)

7.3.3 Pin Auto-Wait Mode

Pin auto-wait mode is selected when $WMS1 = 1$ and $WMS0 = 1$. In this mode the \overline{WAIT} function of the PA_4/\overline{WAIT} pin is used automatically. When the CPU or DTC accesses the external three-state-access address space, if the \overline{WAIT} pin is low the number of wait states indicated by bits $WC1$ and $WC0$ are inserted.

This mode offers a simple way to interface a low-speed device: wait states can be inserted by routing the address strobe signal (\overline{AS}) and a decoded address signal to the \overline{WAIT} pin.

Figure 7-4 shows the timing of operation in this mode when the wait count is 1 ($WC1 = 0$, $WC0 = 1$).

In pin auto-wait mode the \overline{WAIT} pin is sampled only once, on the falling edge of the system clock (ϕ) in the T_2 state. If the \overline{WAIT} signal is low at this time, the wait-state controller inserts the number of wait states indicated by bits $WC1$ and $WC0$. The \overline{WAIT} pin is not sampled during the T_W and T_3 states, so no additional wait states are inserted even if the \overline{WAIT} signal continues to be held low.

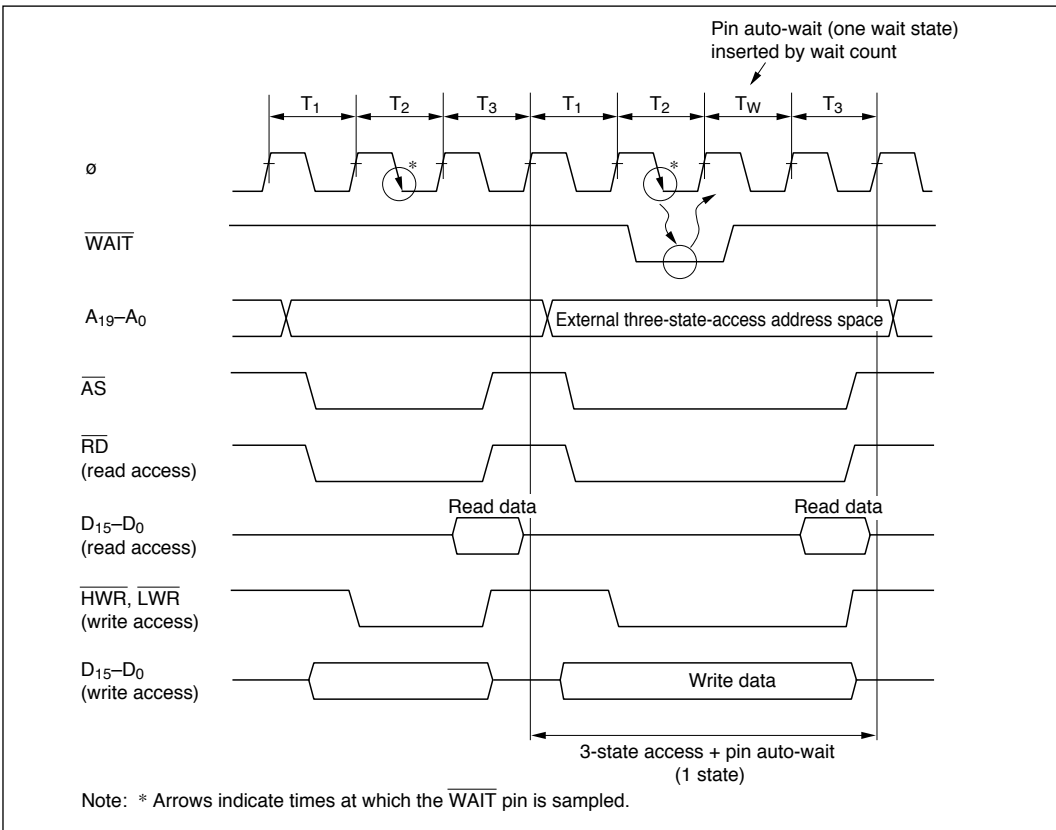

Figure 7-4 Pin Auto-Wait Mode
(Example of External 16-Bit-Bus, Three-State-Access Address Space)

Section 8 Clock Pulse Generator

8.1 Overview

The H8/538F has a built-in clock pulse generator (CPG) consisting of an oscillator circuit, a duty correction circuit, and prescalers that generate clock signals for the on-chip supporting modules.

8.1.1 Block Diagram

Figure 8-1 shows a block diagram of the clock pulse generator.

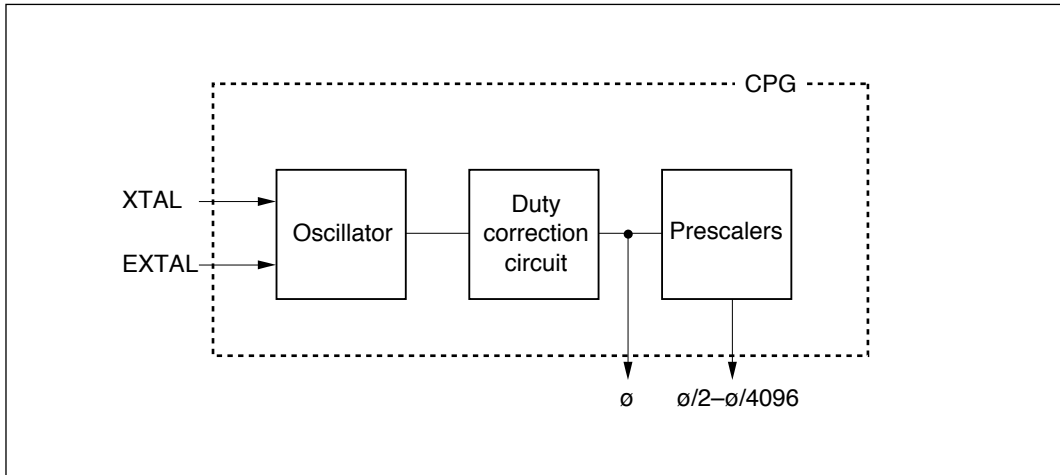

Figure 8-1 Block Diagram of Clock Pulse Generator

8.2 Oscillator Circuit

Clock pulses can be generated by connecting a crystal resonator to the clock oscillator circuit, or by supplying an external clock signal. These two methods are described next.

8.2.1 Connecting a Crystal Resonator

(1) Circuit Configuration: A crystal resonator can be connected as in the example in figure 8-2. An AT-cut parallel resonating crystal should be used. See table 8-1 for the damping resistance.

Figure 8-2 Connection of Crystal Resonator (Example)

Table 8-1 Damping Resistance (Examples)

Frequency (MHz)	2	4	8	12	16
Rd max (Ω)	1 k	500	200	0	0

(2) Crystal Resonator: Figure 8-3 shows an equivalent circuit of the crystal resonator. The crystal resonator should have the characteristics listed in table 8-2.

Figure 8-3 Crystal Resonator Equivalent Circuit

Table 8-2 Crystal Resonator Parameters

Frequency (MHz)	2	4	8	12	16
Rs max (Ω)	500	120	80	60	50
C ₀ (pF)	7 pF max				

(3) Notes on Board Design: When a crystal resonator is connected, the following points should be noted:

- Other signal lines should be routed away from the oscillator circuit to prevent induction from interfering with correct oscillation. See figure 8-4.
- When the board is designed, the crystal resonator and its load capacitors should be placed as close as possible to the XTAL and EXTAL pins.

Figure 8-4 Example of Incorrect Board Design

8.2.2 External Clock Input

(1) Circuit Configuration: An external clock signal can be input at the EXTAL pin as shown in the examples in figure 8-5. In example b, the clock should be held high in standby mode.

If the XTAL pin is left open, the stray capacitance should not exceed 10 pF.

a. XTAL pin left open

b. Complementary clock input at XTAL pin

Figure 8-5 External Clock Input (Examples)

(2) **External Clock:** The external clock frequency should be equal to the system clock frequency (ϕ). Table 8-3 and figure 8-6 indicate the clock timing.

Table 8-3 Clock Timing

Item	Symbol	$V_{CC} = 2.7 \text{ to } 5.5 \text{ V}$		$V_{CC} = 5.0 \text{ V } \pm 10\%$		Unit	Test Conditions
		Min	Max	Min	Max		
External clock input low pulse width	t_{EXL}	40	—	20	—	ns	Figure 8-6
External clock input high pulse width	t_{EXH}	40	—	20	—	ns	
External clock rise time	t_{EXr}	—	10	—	5	ns	
External clock fall time	t_{EXf}	—	10	—	5	ns	

Figure 8-6 External Clock Input Timing

Section 9 I/O Ports

9.1 Overview

The H8/538F has twelve I/O ports. Ports 1, 2, 4, 5, 7, B, and C are eight-bit input/output ports. Port 3 is a six-bit input/output port. Port 6 is a five-bit input/output port. Port A is a seven-bit input/output port. Port 8 is a four-bit input port. Port 9 is an eight-bit input port.

These ports are multiplexed with inputs and outputs of the on-chip supporting modules. The functions of ports 1, 2, A, B, and C also differ depending on the operating mode.

Each port has a data direction register (DDR) for selecting input or output, and a data register (DR) for holding output data. In addition to DR and DDR, port A has a bus release control register (BRCR), and ports B and C have pull-up transistor control registers (PBPCR and PCPCR).

Ports 1, 2, A, B, and C can drive one TTL load and a 90-pF capacitive load. Ports 3 to 7 can drive one TTL load and a 30-pF capacitive load. Ports 3 and 5 can drive LEDs (with 10-mA current sink). Ports 4 and 5 have Schmitt-trigger input circuits.

Table 9-1 summarizes ports 1 to C, giving the pin names and functions in each mode.

Table 9-1 Ports 1 to C, Pin Names, and Functions in Each Mode

Port	Description	Pins	Expanded Minimum Modes		Expanded Maximum Modes		Single-Chip Mode Mode 7
			Modes 1 and 6	Mode 2	Modes 3 and 5	Mode 4	
Port 1	8-bit input/output port	P1 ₇ –P1 ₀ / D1 ₅ –D ₈	Data bus (D ₁₅ to D ₈)				General-purpose input/output
Port 2	8-bit input/output port	P2 ₇ –P2 ₀ / D ₇ –D ₀	Data bus (D ₇ to D ₀)	General-purpose input/output	Data bus (D ₇ to D ₀)	Data bus (D ₇ to D ₀)	General-purpose input/output
Port 3	6-bit input/output port	P3 ₅ –P3 ₀ / T2OC ₂ , T2OC ₁ , T1OC ₄ –T1OC ₁	Output (T2OC _{2/1} , T1OC _{4/3/2/1}) from 16-bit integrated-timer pulse unit (IPU), and general-purpose input/output				
Port 4	8-bit input/output port	P4 ₇ /T7IOC ₂ , P4 ₆ /T7IOC ₁ , P4 ₅ /T6IOC ₂ , P4 ₄ /T6IOC ₁ , P4 ₃ /T5IOC ₂ , P4 ₂ /T5IOC ₁ , P4 ₁ /T4IOC ₂ , P4 ₀ /T4IOC ₁	Input and output (T7IOC _{2/1} , T6IOC _{2/1} , T5IOC _{2/1} , T4IOC _{2/1}) for 16-bit integrated-timer pulse unit (IPU), and general-purpose input/output				
Port 5	8-bit input/output port	P5 ₇ –P5 ₀ / T3IOC ₂ , T3IOC ₁ , T2IOC ₂ , T2IOC ₁ , T1IOC ₄ –T1IOC ₁	Input and output (T3IOC _{2/1} , T2IOC _{2/1} , T1IOC _{4/3/2/1}) for 16-bit integrated-timer pulse unit (IPU), and general-purpose input/output				
Port 6	5-bit input/output port	P6 ₄ /TCLK ₃ , P6 ₃ /TCLK ₂ , P6 ₂ /TCLK ₁ , P6 ₁ /IRQ ₃ , P6 ₀ /IRQ ₂	Clock input (TCLK _{3/2/1}) for 16-bit integrated-timer pulse unit (IPU), external interrupt input (IRQ _{3/2}), and general-purpose input/output				
Port 7	8-bit input/output port	P7 ₇ /SCK ₂ , P7 ₆ /SCK ₁ , P7 ₅ /RXD ₂ , P7 ₄ /TXD ₂ , P7 ₃ /RXD ₁ , P7 ₂ /TXD ₁ , P7 ₁ /IRQ ₁ / ADTRG, P7 ₀ /IRQ ₀	Input and output (SCK _{1/2} , TXD _{1/2} , RXD _{1/2}) for serial communication interfaces 1 and 2 (SCI _{1/2}), external interrupt input (IRQ _{1/0}), A/D converter trigger input (ADTRG), and general-purpose input/output				
Port 8	4-bit input port	P8 ₃ –P8 ₀ / AN ₁₁ –AN ₈	Analog input for A/D converter (AN ₁₁ to AN ₈) and general-purpose input				
Port 9	8-bit input port	P9 ₇ –P9 ₀ / AN ₇ –AN ₀	Analog input for A/D converter (AN ₇ to AN ₀) and general-purpose input				

Table 9-1 Ports 1 to C, Pin Names, and Functions in Each Mode (cont)

Port	Description	Pins	Expanded Minimum Modes		Expanded Maximum Modes		Single-Chip Mode Mode 7
			Modes 1 and 6	Mode 2	Modes 3 and 5	Mode 4	
Port A	7-bit input/output port	PA ₆ /T3OC ₂ /BACK, PA ₅ /T3OC ₁ /BREQ, PA ₄ /WAIT	Output from 16-bit integrated-timer pulse unit (IPU), general-purpose input/output, and BACK, BREQ, and WAIT input and output if enabled by settings in bus release control register (BRCR) and wait control register (WCR)				16-bit integrated-timer pulse unit (IPU) output, and general-purpose input/output (PA ₄ : general-purpose input/output only)
		PA ₃ /A ₁₉ /T5OC ₂ , PA ₂ /A ₁₈ /T5OC ₁ , PA ₁ /A ₁₇ /T4OC ₂ , PA ₀ /A ₁₆ /T4OC ₁	Output (T5OC _{2/1} , T4OC _{2/1}) from 16-bit integrated-timer pulse unit (IPU), and general-purpose input/output		Page address output (A ₁₉ to A ₁₆)	Page address output (A ₁₉ to A ₁₆) when DDR = 1, general-purpose input when DDR = 0	
Port B	8-bit input/output port	PB ₇ –PB ₀ / A ₁₅ –A ₈	Address output (A ₁₅ to A ₀)	Address output (A ₁₅ to A ₀) when DDR = 1, general-purpose input when DDR = 0	Address output (A ₁₅ to A ₀)	Address output (A ₁₅ to A ₀) when DDR = 1, general-purpose input when DDR = 0	General-purpose input/output
Port C	8-bit input/output port	PC ₇ –PC ₀ / A ₇ –A ₀					

9.2 Port 1

9.2.1 Overview

Port 1 is an eight-bit general-purpose input/output port in mode 7. In modes 1 to 6, port 1 is a data bus (D₁₅ to D₈).

Pins in port 1 can drive one TTL load and a 90-pF capacitive load. They can also drive a Darlington transistor pair.

Figure 9-1 summarizes the pin functions. Figure 9-2 shows examples of output loads for port 1.

Figure 9-1 Port 1 Pin Functions

(1) One TTL load or four LS-TTL loads

(2) Darlington transistor pair

Figure 9-2 Examples of Port 1 Output Loads

9.2.2 Register Descriptions

Table 9-2 summarizes the registers of port 1.

Table 9-2 Port 1 Registers

Address	Name	Abbreviation	R/W	Initial Value
H'FE80	Port 1 data direction register	P1DDR	W	H'00
H'FE82	Port 1 data register	P1DR	R/W	H'00

(1) Port 1 Data Direction Register: The port 1 data direction register (P1DDR) is an eight-bit register. Each bit selects input or output for one pin in port 1. These input/output designations are valid only in mode 7.

Bit	7	6	5	4	3	2	1	0
	P1 ₇ DDR	P1 ₆ DDR	P1 ₅ DDR	P1 ₄ DDR	P1 ₃ DDR	P1 ₂ DDR	P1 ₁ DDR	P1 ₀ DDR
Initial value	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W

A pin in port 1 becomes an output pin if the corresponding P1DDR bit is set to 1, and an input pin if this bit is cleared to 0. P1DDR is a write-only register. All bits always return the value 1 when read.

P1DDR is initialized to H'00 by a reset and in hardware standby mode. P1DDR is not initialized in software standby mode.

(2) Port 1 Data Register: The port 1 data register (P1DR) is an eight-bit register that stores data for pins P1₀ to P1₇. P1DR is used only in mode 7. In modes 1 to 6, the bit values in P1DR cannot be modified and always read 1.

Bit	7	6	5	4	3	2	1	0
	P1 ₇	P1 ₆	P1 ₅	P1 ₄	P1 ₃	P1 ₂	P1 ₁	P1 ₀
Initial value	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

When a bit in P1DDR is set to 1, the corresponding P1DR bit value is output at the corresponding pin. If port 1 is read the value in P1DR is returned, regardless of the actual state of the pin.

When a bit in P1DDR is cleared to 0, it is possible to write to the corresponding P1DR bit but the value is not output at the pin. If P1DR is read the value at the pin is returned, regardless of the value written in P1DR.

P1DR is initialized to H'00 by a reset and in hardware standby mode. P1DR is not initialized in software standby mode.

9.2.3 Pin Functions in Each Mode

The functions of port 1 differ between the externally expanded modes (modes 1 to 6) and single-chip mode (mode 7). The pin functions in each mode are described below.

(1) Pin Functions in Externally Expanded Modes (Modes 1 to 6): The settings in P1DDR are ignored. Port 1 automatically becomes a bidirectional data bus. Figure 9-3 shows the pin functions in modes 1 to 6.

Figure 9-3 Pin Functions in Modes 1 to 6

(2) Pin Functions in Single-Chip Mode (Mode 7): Port 1 consists of general-purpose input/output pins. Input or output can be selected separately for each pin. A pin becomes an output pin if the corresponding P1DDR bit is set to 1 and an input pin if this bit is cleared to 0. Figure 9-4 shows the pin functions in mode 7.

Figure 9-4 Pin Functions in Mode 7

(3) Software Standby Mode: Transition to software standby does not change the pin functions in single-chip mode. In the externally expanded modes, port 1 is in the high-impedance state during software standby.

9.2.4 Port 1 Read/Write Operations

P1DR and P1DDR have different read/write functions depending on whether port 1 is used as a data bus (D_{15} to D_8) or for general-purpose input or output ($P1_7$ to $P1_0$). The operating states and functions of port 1 are described next.

(1) Data Bus (Modes 1 to 6): Figure 9-5 shows a block diagram illustrating the data-bus function. Table 9-3 indicates register read/write data. When port 1 operates as a data bus, the values in the port 1 data register (P1DR) have no effect on the bus lines. When read, P1DR returns all 1s.

Figure 9-5 Data Bus: D_{15} to D_8 (Modes 1 to 6)

Table 9-3 Register Read/Write Data

	Read	Write
P1DR	Always 1	Don't care

(2) Input Port (Mode 7): Figure 9-6 shows a block diagram illustrating the general-purpose input function. Table 9-4 indicates register read/write data. Values written in the port 1 data register (P1DR) have no effect on general-purpose input lines. When read, P1DR returns the value at the pin.

Figure 9-6 Input Port (Mode 7)

Table 9-4 Register Read/Write Data

	Read	Write
P1DR	Pin value	Don't care

(3) Output Port (Mode 7): Figure 9-7 shows a block diagram illustrating the general-purpose output function. Table 9-5 indicates register read/write data. The value written in the port 1 data register (P1DR) is output at the pin. When read, P1DR returns the value written in P1DR.

Figure 9-7 Output Port (Mode 7)

Table 9-5 Register Read/Write Data

	Read	Write
P1DR	P1DR value	Value output at pin

9.3 Port 2

9.3.1 Overview

Port 2 is an eight-bit general-purpose input/output port in modes 2 and 7. In modes 1, 3, 4, 5, and 6, port 2 is a data bus (D₇ to D₀).

Pins in port 2 can drive one TTL load and a 90-pF capacitive load. They can also drive a Darlington transistor pair.

Figure 9-8 summarizes the pin functions. Figure 9-9 shows examples of output loads for port 2.

Figure 9-8 Port 2 Pin Functions

(1) One TTL load or four LS-TTL loads

(2) Darlington transistor pair

Figure 9-9 Examples of Port 2 Output Loads

9.3.2 Register Descriptions

Table 9-6 summarizes the registers of port 2.

Table 9-6 Port 2 Registers

Address	Name	Abbreviation	R/W	Initial Value
H'FE81	Port 2 data direction register	P2DDR	W	H'00
H'FE83	Port 2 data register	P2DR	R/W	H'00

(1) Port 2 Data Direction Register: The port 2 data direction register (P2DDR) is an eight-bit register. Each bit selects input or output for one pin in port 2. These input/output designations are valid only in modes 2 and 7.

Bit	7	6	5	4	3	2	1	0
	P2 ₇ DDR	P2 ₆ DDR	P2 ₅ DDR	P2 ₄ DDR	P2 ₃ DDR	P2 ₂ DDR	P2 ₁ DDR	P2 ₀ DDR
Initial value	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W

A pin in port 2 becomes an output pin if the corresponding P2DDR bit is set to 1, and an input pin if this bit is cleared to 0. P2DDR is a write-only register. All bits always return the value 1 when read.

P2DDR is initialized to H'00 by a reset and in hardware standby mode. P2DDR is not initialized in software standby mode.

(2) Port 2 Data Register: The port 2 data register (P2DR) is an eight-bit register that stores data for pins P2₇ to P2₀. P2DR is used only in modes 2 and 7. In modes 1, 3, 4, 5, and 6, the bit values in P2DR cannot be modified and always read 1.

Bit	7	6	5	4	3	2	1	0
	P2 ₇	P2 ₆	P2 ₅	P2 ₄	P2 ₃	P2 ₂	P2 ₁	P2 ₀
Initial value	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

When a bit in P2DDR is set to 1, the corresponding P2DR bit value is output at the corresponding pin. If port 2 is read the value in P2DR is returned, regardless of the actual state of the pin.

When a bit in P2DDR is cleared to 0, it is possible to write to the corresponding P2DR bit but the value is not output at the pin. If P2DR is read the value at the pin is returned, regardless of the value written in P2DR.

P2DR is initialized to H'00 by a reset and in hardware standby mode. P2DR is not initialized in software standby mode.

9.3.3 Pin Functions in Each Mode

The functions of port 2 differ between modes 1, 3, 4, 5, and 6 on one hand, and modes 2 and 7 on the other hand. The pin functions in each mode group are described below.

(1) Pin Functions in Modes 1, 3, 4, 5, and 6: The settings in P2DDR are ignored. Port 2 automatically becomes a bidirectional data bus. Figure 9-10 shows the pin functions in modes 1, 3, 4, 5, and 6.

Figure 9-10 Pin Functions in Modes 1, 3, 4, 5, and 6

(2) Pin Functions in Modes 2 and 7: Port 2 consists of general-purpose input/output pins. Input or output can be selected separately for each pin. A pin becomes an output pin if the corresponding P2DDR bit is set to 1 and an input pin if this bit is cleared to 0. Figure 9-11 shows the pin functions in modes 2 and 7.

Figure 9-11 Pin Functions in Modes 2 and 7

(3) Software Standby Mode: Transition to software standby does not change the pin functions in single-chip mode. In the externally expanded modes, port 2 is in the high-impedance state during software standby.

9.3.4 Port 2 Read/Write Operations

P2DR and P2DDR have different read/write functions depending on whether port 2 is used as a data bus (D₇ to D₀) or for general-purpose input or output (P2₇ to P2₀). The operating states and functions of port 2 are described next.

(1) Data Bus (All Pins: Modes 1, 3, 4, 5, and 6): Figure 9-12 shows a block diagram illustrating the data-bus function. Table 9-7 indicates register read/write data. When port 2 operates as a data bus, the values in the port 2 data register (P2DR) have no effect on the bus lines. When read, P2DR returns all 1s.

Figure 9-12 Data Bus: D₇ to D₀ (Modes 1, 3, 4, 5, and 6)

Table 9-7 Register Read/Write Data

	Read	Write
P2DR	Always 1	Don't care

(2) Input Port (Modes 2 and 7): Figure 9-13 shows a block diagram illustrating the general-purpose input function. Table 9-8 indicates register read/write data. Values written in the port 2 data register (P2DR) have no effect on general-purpose input lines. When read, P2DR returns the value at the pin.

Figure 9-13 Input Port (Modes 2 and 7)

Table 9-8 Register Read/Write Data

	Read	Write
P2DR	Pin value	Don't care

(3) Output Port (Modes 2 and 7): Figure 9-14 shows a block diagram illustrating the general-purpose output function. Table 9-9 indicates register read/write data. The value written in the port 2 data register (P2DR) is output at the pin. When read, P2DR returns the value written in P2DR.

Figure 9-14 Output Port (Modes 2 and 7)

Table 9-9 Register Read/Write Data

	Read	Write
P2DR	P2DR value	Value output at pin

9.4 Port 3

9.4.1 Overview

Port 3 is a six-bit input/output port that is multiplexed with output compare pins (T2OC₂, T2OC₁, T1OC₄ to T1OC₁) of the 16-bit integrated-timer pulse unit (IPU). Figure 9-15 summarizes the pin functions.

Pins in port 3 can drive one TTL load and a 30-pF capacitive load. They can also drive a Darlington transistor pair or LED (with 10-mA current sink).

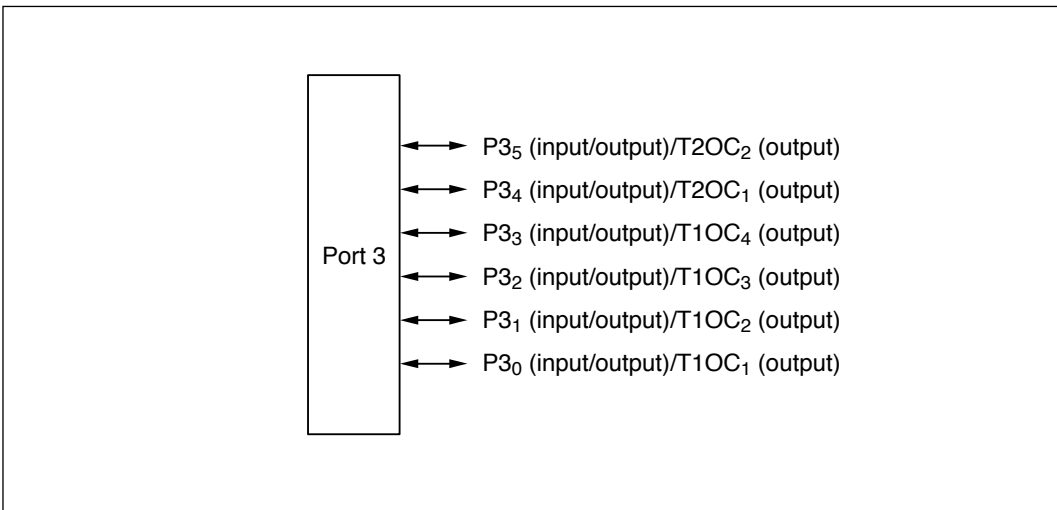

**Figure 9-15 Port 3 Pin Functions**

Figure 9-16 shows examples of output loads for port 3.

(1) One TTL load or four LS-TTL loads

(2) Darlington transistor pair

(3) LED driving circuit

Figure 9-16 Examples of Port 3 Output Loads

9.4.2 Register Descriptions

Table 9-10 summarizes the registers of port 3.

Table 9-10 Port 3 Registers

Address	Name	Abbreviation	R/W	Initial Value
H'FE84	Port 3 data direction register	P3DDR	W	H'C0
H'FE86	Port 3 data register	P3DR	R/W	H'C0

(1) Port 3 Data Direction Register: The port 3 data direction register (P3DDR) is an eight-bit register. Each bit selects input or output for one pin.

Bit	7	6	5	4	3	2	1	0
	—	—	P3 ₅ DDR	P3 ₄ DDR	P3 ₃ DDR	P3 ₂ DDR	P3 ₁ DDR	P3 ₀ DDR
Initial value	1	1	0	0	0	0	0	0
R/W	—	—	W	W	W	W	W	W

A pin in port 3 becomes an output pin if the corresponding P3DDR bit is set to 1, and an input pin if this bit is cleared to 0. P3DDR is a write-only register. All bits always return the value 1 when read.

P3DDR is initialized to H'C0 by a reset and in hardware standby mode. P3DDR is not initialized in software standby mode.

(2) Port 3 Data Register: The port 3 data register (P3DR) is an eight-bit register that stores data for pins P3₅ to P3₀.

Bit	7	6	5	4	3	2	1	0
	—	—	P3 ₅	P3 ₄	P3 ₃	P3 ₂	P3 ₁	P3 ₀
Initial value	1	1	0	0	0	0	0	0
R/W	—	—	R/W	R/W	R/W	R/W	R/W	R/W

When a bit in P3DDR is set to 1, the corresponding P3DR bit value is output at the corresponding pin. If port 3 is read the value in P3DR is returned, regardless of the actual state of the pin.

When a bit in P3DDR is cleared to 0, it is possible to write to the corresponding P3DR bit but the value is not output at the pin. If P3DR is read the value at the pin is returned, regardless of the value written in P3DR.

P3DR is initialized to H'C0 by a reset and in hardware standby mode. P3DR is not initialized in software standby mode.

9.4.3 Pin Functions in Each Mode

In all modes port 3 can be used for general-purpose input or output, or for the output compare function of the 16-bit integrated-timer pulse unit (IPU).

- (1) Pin Functions in Modes 1 to 7:** When a pin is used for IPU output, the setting in P3DDR is ignored. T1OC₁ to T1OC₄, T2OC₁, or T2OC₂ output is selected automatically. For methods of selecting pin functions, see appendix D “Pin Function Selection.”
- (2) Software Standby Mode:** Transition to software standby mode initializes the on-chip supporting modules, so port 3 becomes an input or output port according to P3DDR and P3DR.

9.4.4 Port 3 Read/Write Operations

P3DR and P3DDR have different read/write functions depending on whether port 3 is used for the output compare function (T1OC₁ to T1OC₄, T2OC₁, T2OC₂) of the 16-bit integrated-timer pulse unit (IPU) or general-purpose input or output (P3₅ to P3₀). The operating states and functions of port 3 are described next.

- (1) Input Port (Modes 1 to 7):** Figure 9-17 shows a block diagram illustrating the general-purpose input function. Table 9-11 indicates register read/write data. Values written in the port 3 data register (P3DR) have no effect on general-purpose input lines. When read, P3DR returns the value at the pin.

Figure 9-17 Input Port (Modes 1 to 7)

Table 9-11 Register Read/Write Data

	Read	Write
P3DR	Pin value	Don't care

- (2) Output Port (Modes 1 to 7):** Figure 9-18 shows a block diagram illustrating the general-purpose output function. Table 9-12 indicates register read/write data. The value written in the port 3 data register (P3DR) is output at the pin. When read, P3DR returns the value written in P3DR.

Figure 9-18 Output Port (Modes 1 to 7)

Table 9-12 Register Read/Write Data

	Read	Write
P3DR	P3DR value	Value output at pin

(3) Timer Output Pins (Modes 1 to 7): Figure 9-19 shows a block diagram illustrating the timer output function. Table 9-13 indicates register read/write data. When a pin in port 3 is used for timer output, the setting in the port 3 data direction register (P3DDR) is ignored. The value in the port 3 data register (P3DR) has no effect on the timer output. P3DR can be read to monitor the timer output level (T1OC₁ to T1OC₄, T2OC₁, T2OC₂).

Figure 9-19 Timer Output Pins (Modes 1 to 7)

Table 9-13 Register Read/Write Data

	Read	Write
P3DR	Pin value	Don't care

9.5 Port 4

9.5.1 Overview

Port 4 is an eight-bit input/output port that is multiplexed with output compare and input capture pins (T7IOC_{2/1}, T6IOC_{2/1}, T5IOC_{2/1}, T4IOC_{2/1}) of the 16-bit integrated-timer pulse unit (IPU). Figure 9-20 summarizes the pin functions.

Pins in port 4 can drive one TTL load and a 30-pF capacitive load. They can also drive a Darlington transistor pair. P4₇ to P4₀ have Schmitt-trigger input circuits.

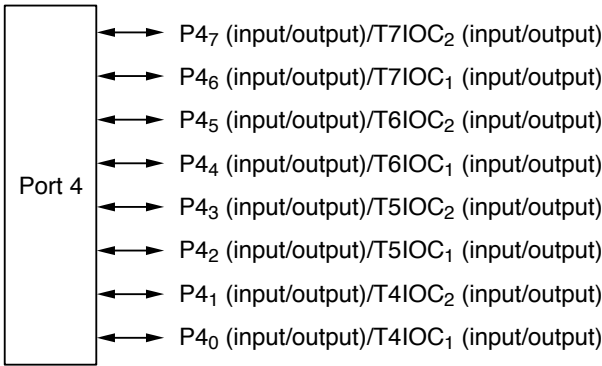

Figure 9-20 Port 4 Pin Functions

Figure 9-21 shows examples of output loads for port 4.

(1) One TTL load or four LS-TTL loads (2) Darlington transistor pair

Figure 9-21 Examples of Port 4 Output Loads

9.5.2 Register Descriptions

Table 9-14 summarizes the registers of port 4.

Table 9-14 Port 4 Registers

Address	Name	Abbreviation	R/W	Initial Value
H'FE85	Port 4 data direction register	P4DDR	W	H'00
H'FE87	Port 4 data register	P4DR	R/W	H'00

(1) Port 4 Data Direction Register: The port 4 data direction register (P4DDR) is an eight-bit register. Each bit selects input or output for one pin.

Bit	7	6	5	4	3	2	1	0
	P4 ₇ DDR	P4 ₆ DDR	P4 ₅ DDR	P4 ₄ DDR	P4 ₃ DDR	P4 ₂ DDR	P4 ₁ DDR	P4 ₀ DDR
Initial value	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W

A pin in port 4 becomes an output pin if the corresponding P4DDR bit is set to 1, and an input pin if this bit is cleared to 0. P4DDR is a write-only register. All bits always return the value 1 when read.

P4DDR is initialized to H'00 by a reset and in hardware standby mode. P4DDR is not initialized in software standby mode.

(2) Port 4 Data Register: The port 4 data register (P4DR) is an eight-bit register that stores data for pins P4₇ to P4₀.

Bit	7	6	5	4	3	2	1	0
	P4 ₇	P4 ₆	P4 ₅	P4 ₄	P4 ₃	P4 ₂	P4 ₁	P4 ₀
Initial value	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

When a bit in P4DDR is set to 1, the corresponding P4DR bit value is output at the corresponding pin. If port 4 is read the value in P4DR is returned, regardless of the actual state of the pin.

When a bit in P4DDR is cleared to 0, it is possible to write to the corresponding P4DR bit but the value is not output at the pin. If P4DR is read the value at the pin is returned, regardless of the value written in P4DR.

P4DR is initialized to H'00 by a reset and in hardware standby mode. P4DR is not initialized in software standby mode.

9.5.3 Pin Functions in Each Mode

In all modes port 4 can be used for general-purpose input or output, or for the input capture and output compare functions of the 16-bit integrated-timer pulse unit (IPU).

(1) Pin Functions in Modes 1 to 7: When a pin is used for the IPU output-compare function, the setting in P4DDR has no effect. T4IOC₁, T4IOC₂, T5IOC₁, T5IOC₂, T6IOC₁, T6IOC₂, T7IOC₁, or T7IOC₂ output is selected automatically. When the IPU input capture function is selected, the P4DDR setting is valid and the pin can simultaneously function as a general-purpose input or output port. For methods of selecting pin functions, see appendix D “Pin Function Selection.”

(2) Software Standby Mode: Transition to software standby mode initializes the on-chip supporting modules, so port 4 becomes an input or output port according to P4DDR and P4DR.

9.5.4 Port 4 Read/Write Operations

P4DR and P4DDR have different read/write functions depending on whether port 4 is used for the input capture or output compare function (T4IOC_{1/2}, T5IOC_{1/2}, T6IOC_{1/2}, T7IOC_{1/2}) of the 16-bit integrated-timer pulse unit (IPU) or for general-purpose input or output (P4₇ to P4₀). The operating states and functions of port 4 are described next.

(1) Input Port (Modes 1 to 7): Figure 9-22 shows a block diagram illustrating the general-purpose input function. Table 9-15 indicates register read/write data. Values written in the port 4 data register (P4DR) have no effect on general-purpose input lines. When read, P4DR returns the value at the pin.

Figure 9-22 Input Port (Modes 1 to 7)

Table 9-15 Register Read/Write Data

	Read	Write
P4DR	Pin value	Don't care

(2) Output Port (Modes 1 to 7): Figure 9-23 shows a block diagram illustrating the general-purpose output function. Table 9-16 indicates register read/write data. The value written in the port 4 data register (P4DR) is output at the pin. When read, P4DR returns the value written in P4DR.

Figure 9-23 Output Port (Modes 1 to 7)

Table 9-16 Register Read/Write Data

	Read	Write
P4DR	P4DR value	Value output at pin

(3) Timer Output Pins (Modes 1 to 7): Figure 9-24 shows a block diagram illustrating the output compare function. Table 9-17 indicates register read/write data. When a pin in port 4 is used for output compare, the value in the port 4 data register (P4DR) has no effect on the timer output. P4DR can be read to monitor the timer output level (T4IOC₁, T4IOC₂, T5IOC₁, T5IOC₂, T6IOC₁, T6IOC₂, T7IOC₁, T7IOC₂).

Figure 9-24 Output Compare Pins (Modes 1 to 7)

Table 9-17 Register Read/Write Data

	Read	Write
P4DR	Pin value	Don't care

(4) Timer Input Combined with General-Purpose Output (Modes 1 to 7): Figure 9-25 shows a block diagram illustrating the input capture function when combined with general-purpose output. Table 9-18 indicates register read/write data. An input capture pin can also function as an output port, in which case the output value is input to the timer.

Table 9-19 Register Read/Write Data

	Read	Write
P4DR	Timer input	Value output at pin

9.6 Port 5

9.6.1 Overview

Port 5 is an eight-bit input/output port that is multiplexed with output compare and input capture pins (T3IOC_{2/1}, T2IOC_{2/1}, T1IOC_{4/3/2/1}) of the 16-bit integrated-timer pulse unit (IPU). Figure 9-27 summarizes the pin functions.

Pins in port 5 can drive one TTL load and a 30-pF capacitive load. They can also drive a Darlington transistor pair or LED (with 10-mA current sink). Inputs are Schmitt-triggered.

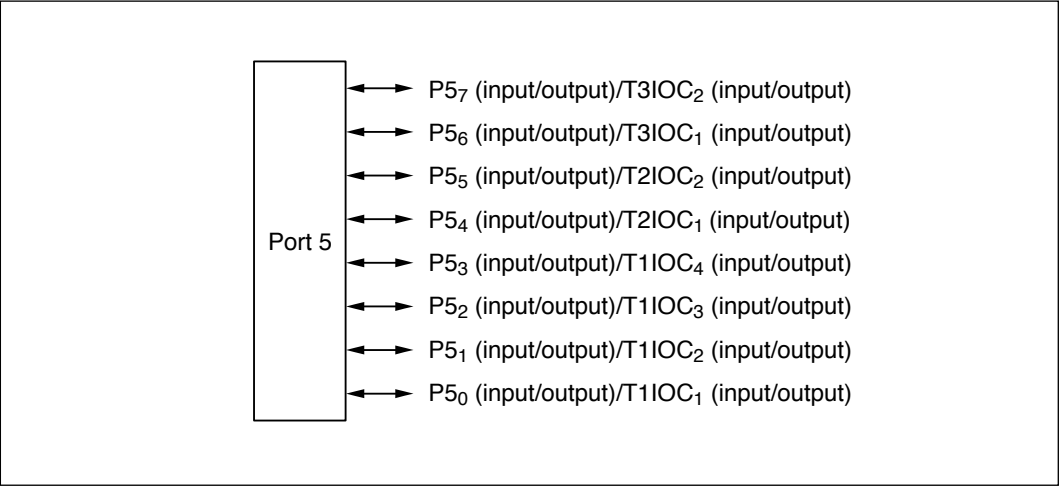

Figure 9-27 Port 5 Pin Functions

Figure 9-28 shows examples of output loads for port 5.

(1) One TTL load or four LS-TTL loads

(2) Darlington transistor pair

(3) LED driving circuit

Figure 9-28 Examples of Port 5 Output Loads

9.6.2 Register Descriptions

Table 9-20 summarizes the registers of port 5.

Table 9-20 Port 5 Registers

Address	Name	Abbreviation	R/W	Initial Value
H'FE88	Port 5 data direction register	P5DDR	W	H'00
H'FE8A	Port 5 data register	P5DR	R/W	H'00

(1) Port 5 Data Direction Register: The port 5 data direction register (P5DDR) is an eight-bit register. Each bit selects input or output for one pin.

Bit	7	6	5	4	3	2	1	0
	P5 ₇ DDR	P5 ₆ DDR	P5 ₅ DDR	P5 ₄ DDR	P5 ₃ DDR	P5 ₂ DDR	P5 ₁ DDR	P5 ₀ DDR
Initial value	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W

A pin in port 5 becomes an output pin if the corresponding P5DDR bit is set to 1, and an input pin if this bit is cleared to 0. P5DDR is a write-only register. All bits always return the value 1 when read.

P5DDR is initialized to H'00 by a reset and in hardware standby mode. P5DDR is not initialized in software standby mode.

(2) Port 5 Data Register: The port 5 data register (P5DR) is an eight-bit register that stores data for pins P5₇ to P5₀.

Bit	7	6	5	4	3	2	1	0
	P5 ₇	P5 ₆	P5 ₅	P5 ₄	P5 ₃	P5 ₂	P5 ₁	P5 ₀
Initial value	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

When a bit in P5DDR is set to 1, the corresponding P5DR bit value is output at the corresponding pin. If port 5 is read the value in P5DR is returned, regardless of the actual state of the pin.

When a bit in P5DDR is cleared to 0, it is possible to write to the corresponding P5DR bit but the value is not output at the pin. If P5DR is read the value at the pin is returned, regardless of the value written in P5DR.

P5DR is initialized to H'00 by a reset and in hardware standby mode. P5DR is not initialized in software standby mode.

9.6.3 Pin Functions in Each Mode

In all modes port 5 can be used for general-purpose input or output, or for the input capture and output compare functions of the 16-bit integrated-timer pulse unit (IPU).

- (1) Pin Functions in Modes 1 to 7:** When a pin is used for the IPU output compare function, the setting in P5DDR is ignored. T1IOC₁ to T1IOC₄, T2IOC₁, T2IOC₂, T3IOC₁, or T3IOC₂ output is selected automatically. When the IPU input capture function is selected, the P5DDR setting is valid and the pin can simultaneously function as a general-purpose input or output port. For methods of selecting pin functions, see appendix D “Pin Function Selection.”
- (2) Software Standby Mode:** Transition to software standby mode initializes the on-chip supporting modules, so port 5 becomes an input or output port according to P5DDR and P5DR.

9.6.4 Port 5 Read/Write Operations

P5DR and P5DDR have different read/write functions depending on whether port 5 is used for the input capture or output compare function (T1IOC_{1/2/3/4}, T2IOC_{1/2}, T3IOC_{1/2}) of the 16-bit integrated-timer pulse unit (IPU) or for general-purpose input or output. The operating states and functions of port 5 are described next.

- (1) Input Port (Modes 1 to 7):** Figure 9-29 shows a block diagram illustrating the general-purpose input function. Table 9-21 indicates register read/write data. Values written in the port 5 data register (P5DR) have no effect on general-purpose input lines. When read, P5DR returns the value at the pin.

Figure 9-29 Input Port (Modes 1 to 7)

Table 9-21 Register Read/Write Data

	Read	Write
P5DR	Pin value	Don't care

- (2) Output Port (Modes 1 to 7):** Figure 9-30 shows a block diagram illustrating the general-purpose output function. Table 9-22 indicates register read/write data. The value written in the port 5 data register (P5DR) is output at the pin. When read, P5DR returns the value written in P5DR.

Figure 9-30 Output Port (Modes 1 to 7)

Table 9-22 Register Read/Write Data

	Read	Write
P5DR	P5DR value	Value output at pin

(3) Timer Output Pins (Modes 1 to 7): Figure 9-31 shows a block diagram illustrating the output compare function. Table 9-23 indicates register read/write data. When a pin in port 5 is used for output compare, the value in the port 5 data register (P5DR) has no effect on the timer output. P5DR can be read to monitor the timer output level (T1IOC₁ to T1IOC₄, T2IOC₁, T2IOC₂, T3IOC₁, T3IOC₂).

9.7 Port 6

9.7.1 Overview

Port 6 is a five-bit input/output port that is multiplexed with the external clock pins (TCLK_{3/2/1}) of the 16-bit integrated-timer pulse unit (IPU), and with external interrupt pins ($\overline{\text{IRQ}}_3$ and $\overline{\text{IRQ}}_2$). Figure 9-34 summarizes the pin functions.

Pins in port 6 can drive one TTL load and a 30-pF capacitive load. They can also drive a Darlington transistor pair.

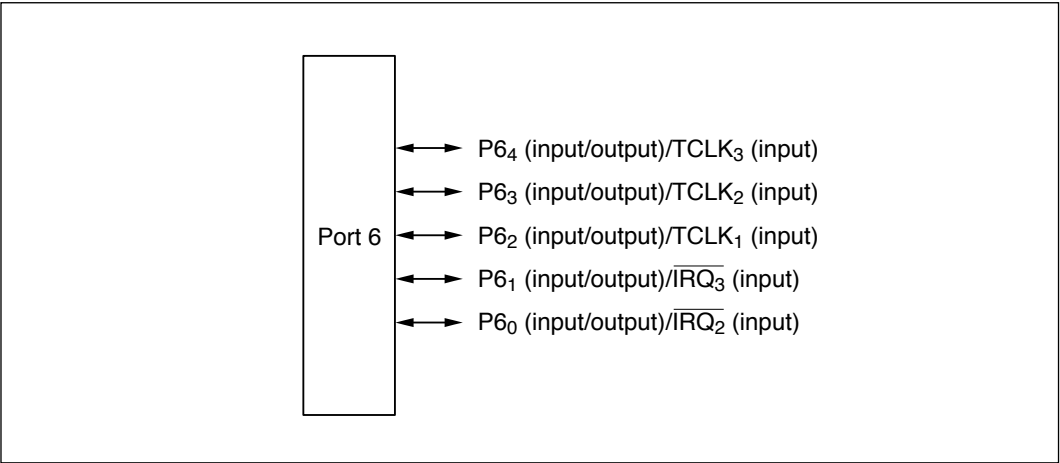

Figure 9-34 Port 6 Pin Functions

Figure 9-35 shows examples of output loads for port 6.

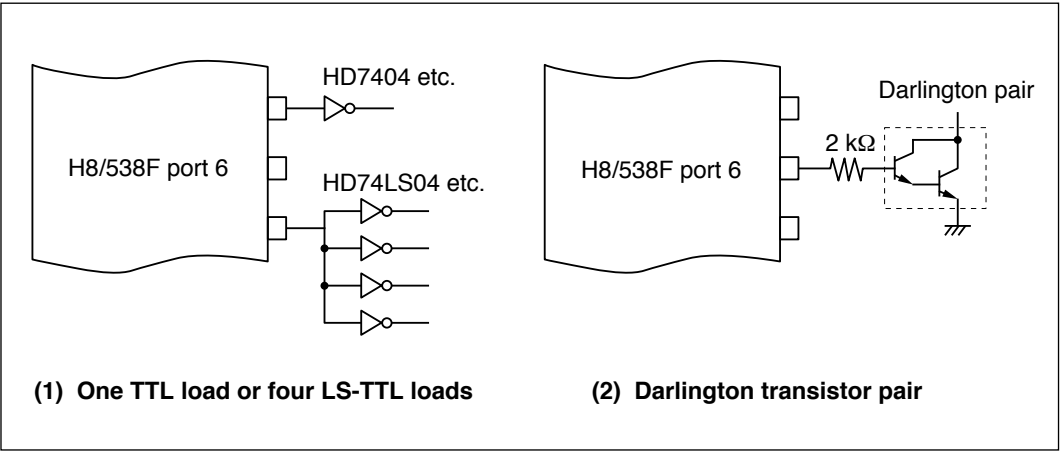

Figure 9-35 Examples of Port 6 Output Loads

9.7.2 Register Descriptions

Table 9-26 summarizes the registers of port 6.

Table 9-26 Port 6 Registers

Address	Name	Abbreviation	R/W	Initial Value
H'FE89	Port 6 data direction register	P6DDR	W	H'E0
H'FE8B	Port 6 data register	P6DR	R/W	H'E0

(1) Port 6 Data Direction Register: The port 6 data direction register (P6DDR) is an eight-bit register. Each bit selects input or output for one pin.

Bit	7	6	5	4	3	2	1	0
	—	—	—	P6 ₄ DDR	P6 ₃ DDR	P6 ₂ DDR	P6 ₁ DDR	P6 ₀ DDR
Initial value	1	1	1	0	0	0	0	0
R/W	—	—	—	W	W	W	W	W

A pin in port 6 becomes an output pin if the corresponding P6DDR bit is set to 1, and an input pin if this bit is cleared to 0. P6DDR is a write-only register. All bits always return the value 1 when read.

P6DDR is initialized to H'E0 by a reset and in hardware standby mode. P6DDR is not initialized in software standby mode.

(2) Port 6 Data Register: The port 6 data register (P6DR) is an eight-bit register that stores data for pins P6₄ to P6₀.

Bit	7	6	5	4	3	2	1	0
	—	—	—	P6 ₄	P6 ₃	P6 ₂	P6 ₁	P6 ₀
Initial value	1	1	1	0	0	0	0	0
R/W	—	—	—	R/W	R/W	R/W	R/W	R/W

When a bit in P6DDR is set to 1, the corresponding P6DR bit value is output at the corresponding pin.

When a bit in P6DDR is cleared to 0, it is possible to write to the corresponding P6DR bit but the value is not output at the pin. If P6DR is read the value at the pin is returned, regardless of the value written in P6DR.

P6DR is initialized to H'E0 by a reset and in hardware standby mode. P6DR is not initialized in software standby mode.

9.7.3 Pin Functions in Each Mode

(1) Pin Functions in Modes 1 to 7: When a pin is used for IPU external clock input (TCLK₃, TCLK₂ and TCLK₁) or external interrupt input ($\overline{\text{IRQ}}_3$ and $\overline{\text{IRQ}}_2$), it can simultaneously function as a general-purpose input or output port. For methods of selecting pin functions, see appendix D “Pin Function Selection.”

(2) Software Standby Mode: Transition to software standby mode initializes the on-chip supporting modules, so port 6 becomes an input or output port according to P6DDR and P6DR.

9.7.4 Port 6 Read/Write Operations

P6DR and P6DDR have different read/write functions depending on whether port 6 is used for external clock input (TCLK₃, TCLK₂ and TCLK₁) to the 16-bit integrated-timer pulse unit (IPU), external interrupt input ($\overline{\text{IRQ}}_3$ and $\overline{\text{IRQ}}_2$), or general-purpose input or output (P6₄ to P6₀). The operating states and functions of port 6 are described next.

(1) Input Port (Modes 1 to 7): Figure 9-36 shows a block diagram illustrating the general-purpose input function. Table 9-27 indicates register read/write data. Values written in the port 6 data register (P6DR) have no effect on general-purpose input lines. When read, P6DR returns the value at the pin.

Figure 9-36 Input Port (Modes 1 to 7)

Table 9-27 Register Read/Write Data

	Read	Write
P6DR	Pin value	Don't care

(2) Output Port (Modes 1 to 7): Figure 9-37 shows a block diagram illustrating the general-purpose output function. Table 9-28 indicates register read/write data. The value written in the port 6 data register (P6DR) is output at the pin. When read, P6DR returns the value written in P6DR.

Figure 9-37 Output Port (Modes 1 to 7)

Table 9-28 Register Read/Write Data

	Read	Write
P6DR	P6DR value	Value output at pin

(3) $\overline{\text{IRQ}}_3$ or $\overline{\text{IRQ}}_2$ Input Combined with General-Purpose Output (P6_1 , P6_0 : Modes 1 to 7): Figure 9-38 shows a block diagram illustrating the $\overline{\text{IRQ}}_3$ and $\overline{\text{IRQ}}_2$ input function of P6_1 and P6_0 when combined with general-purpose output. Table 9-29 indicates register read/write data. When P6_1 and P6_0 are used for $\overline{\text{IRQ}}_3$ and $\overline{\text{IRQ}}_2$ input they can also function as general-purpose output ports. If the general-purpose output function is used, however, output of a falling edge will cause an interrupt.

Figure 9-38 $\overline{\text{IRQ}}_3$ or $\overline{\text{IRQ}}_2$ Input Combined with General-Purpose Output (Modes 1 to 7)

Table 9-29 Register Read/Write Data

P6DR	Pin value	Don't care

9.8 Port 7

9.8.1 Overview

Port 7 is an eight-bit input/output port that is multiplexed with the serial clock input/output pins (SCK2 and SCK1), transmit data output pins (TXD2 and TXD1), and receive data input pins (RXD2 and RXD1) of the serial communication interface (SCI), with external interrupt pins ($\overline{\text{IRQ}}_1$ and $\overline{\text{IRQ}}_0$), and with the external trigger pin ($\overline{\text{ADTRG}}$) of the A/D converter. Figure 9-42 summarizes the pin functions.

Pins in port 7 can drive one TTL load and a 30-pF capacitive load. They can also drive a Darlington transistor pair.

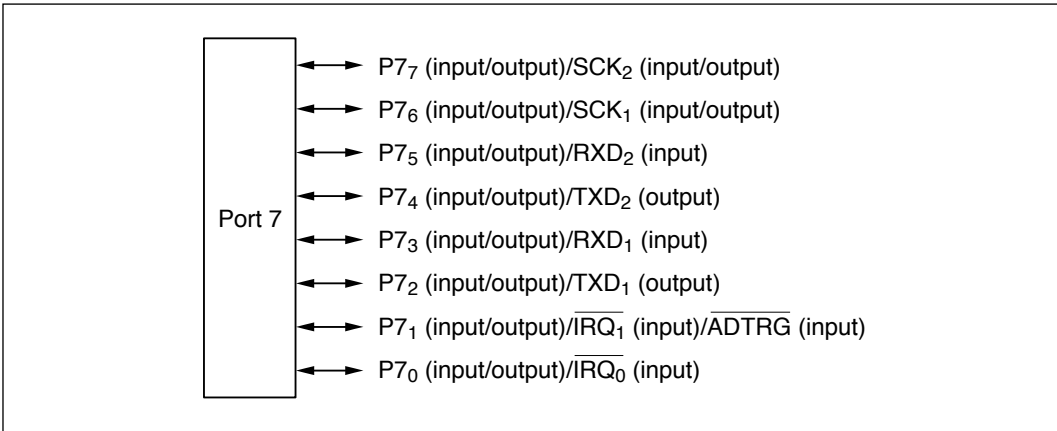

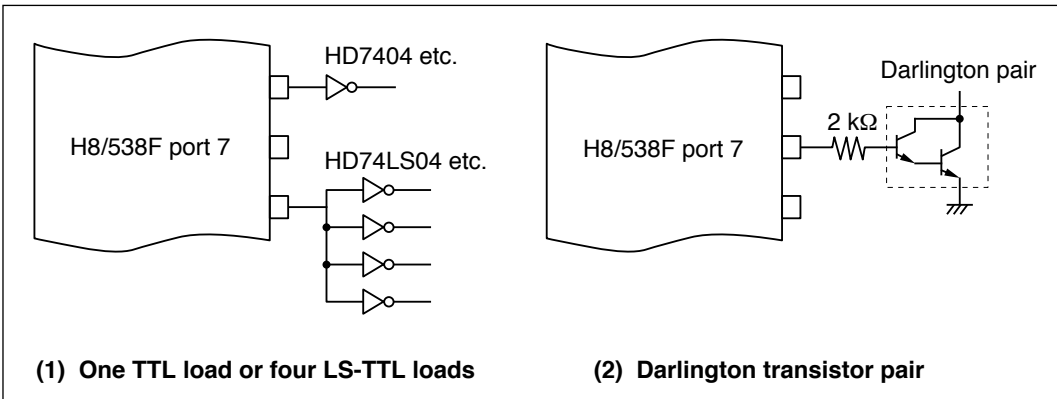

Figure 9-42 Port 7 Pin Functions

Figure 9-43 shows examples of output loads for port 7.

(1) One TTL load or four LS-TTL loads

(2) Darlington transistor pair

Figure 9-43 Examples of Port 7 Output Loads

9.8.2 Register Descriptions

Table 9-33 summarizes the registers of port 7.

Table 9-33 Port 7 Registers

Address	Name	Abbreviation	R/W	Initial Value
H'FE8C	Port 7 data direction register	P7DDR	W	H'00
H'FE8E	Port 7 data register	P7DR	R/W	H'00

(1) Port 7 Data Direction Register: The port 7 data direction register (P7DDR) is an eight-bit register. Each bit selects input or output for one pin.

Bit	7	6	5	4	3	2	1	0
	P7 ₇ DDR	P7 ₆ DDR	P7 ₅ DDR	P7 ₄ DDR	P7 ₃ DDR	P7 ₂ DDR	P7 ₁ DDR	P7 ₀ DDR
Initial value	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W

A pin in port 7 becomes an output pin if the corresponding P7DDR bit is set to 1, and an input pin if this bit is cleared to 0. P7DDR is a write-only register. All bits always return the value 1 when read.

P7DDR is initialized to H'00 by a reset and in hardware standby mode. P7DDR is not initialized in software standby mode.

(2) Port 7 Data Register: The port 7 data register (P7DR) is an eight-bit register that stores data for pins P7₇ to P7₀.

Bit	7	6	5	4	3	2	1	0
	P7 ₇	P7 ₆	P7 ₅	P7 ₄	P7 ₃	P7 ₂	P7 ₁	P7 ₀
Initial value	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

When a bit in P7DDR is set to 1, the corresponding P7DR bit value is output at the corresponding pin. If port 7 is read the value in P7DR is returned, regardless of the actual state of the pin.

When a bit in P7DDR is cleared to 0, it is possible to write to the corresponding P7DR bit but the value is not output at the pin. If P7DR is read the value at the pin is returned, regardless of the value written in P7DR.

P7DR is initialized to H'00 by a reset and in hardware standby mode. P7DR is not initialized in software standby mode.

9.8.3 Pin Functions in Each Mode

(1) Pin Functions in Modes 1 to 7: When a pin is used for input or output by the serial communication interface (SCI), the P7DDR setting is ignored: the pin is automatically used for serial clock input/output (SCK_{2/1}), transmit data output (TXD_{2/1}), or receive data input (RXD_{2/1}).

When P7₁ and P7₀ are used for external interrupt input ($\overline{\text{IRQ}}_1$ and $\overline{\text{IRQ}}_0$), they can simultaneously function as general-purpose input or output ports. P7₁ can also function as the external trigger signal ($\overline{\text{ADTRG}}$) for the A/D converter.

For methods of selecting pin functions, see appendix D “Pin Function Selection.”

(2) Software Standby Mode: Transition to software standby mode initializes the on-chip supporting modules, so port 7 becomes an input or output port according to P7DDR and P7DR.

9.8.4 Port 7 Read/Write Operations

P7DR and P7DDR have different read/write functions depending on whether port 7 is used for output of transmit data (TXD_{1/2}), input of receive data (RXD_{1/2}), or input or output of serial clocks (SCK_{1/2}) for the serial communication interface, external interrupt input ($\overline{\text{IRQ}}_{1/0}$), or general-purpose input or output. The operating states and functions of port 7 are described next.

(1) Input Port (Modes 1 to 7): Figure 9-44 shows a block diagram illustrating the general-purpose input function. Table 9-34 indicates register read/write data. Values written in the port 7 data register (P7DR) have no effect on general-purpose input lines. When read, P7DR returns the value at the pin.

Figure 9-44 Input Port (Modes 1 to 7)

Table 9-34 Register Read/Write Data

	Read	Write
P7DR	Pin value	Don't care

(2) Output Port (Modes 1 to 7): Figure 9-45 shows a block diagram illustrating the general-purpose output function. Table 9-35 indicates register read/write data. The value written in the port 7 data register (P7DR) is output at the pin. When read, P7DR returns the value written in P7DR.

Figure 9-45 Output Port (Modes 1 to 7)

Table 9-35 Register Read/Write Data

	Read	Write
P7DR	P7DR value	Don't care

(3) $\overline{\text{IRQ}}_1$ or $\overline{\text{IRQ}}_0$ Input Combined with General-Purpose Output (P7_1 , P7_0 : Modes 1 to 7): Figure 9-46 shows a block diagram illustrating the $\overline{\text{IRQ}}_1$ and $\overline{\text{IRQ}}_0$ input function when combined with general-purpose output. Table 9-36 indicates register read/write data. When P7_1 and P7_0 are used for $\overline{\text{IRQ}}_1$ and $\overline{\text{IRQ}}_0$ input they can also function as general-purpose output ports. If the general-purpose output function is used, however, output of a falling edge will cause an interrupt.

Figure 9-46 $\overline{\text{IRQ}}_1$ or $\overline{\text{IRQ}}_0$ Input Combined with General-Purpose Output (Modes 1 to 7)

Table 9-36 Register Read/Write Data

	Read	Write
P7DR	P7DR value	Value output at pin

(4) $\overline{\text{IRQ}}_1$ or $\overline{\text{IRQ}}_0$ Input Combined with General-Purpose Input (P7₁, P7₀: Modes 1 to 7):

Figure 9-47 shows a block diagram illustrating the $\overline{\text{IRQ}}_1$ and $\overline{\text{IRQ}}_0$ input function when combined with general-purpose input. Table 9-37 indicates register read/write data. When P7₁ and P7₀ are used for $\overline{\text{IRQ}}_1$ and $\overline{\text{IRQ}}_0$ input they can also be read as general-purpose input ports, to monitor the input level at $\overline{\text{IRQ}}_1$ or $\overline{\text{IRQ}}_0$.

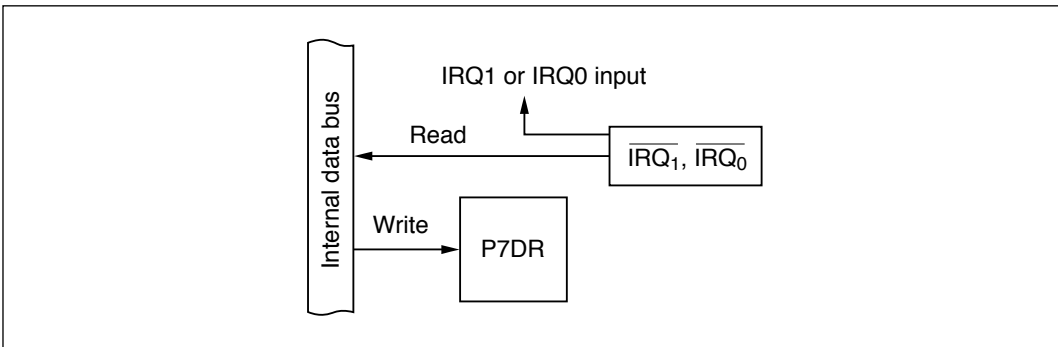

Figure 9-47 $\overline{\text{IRQ}}_1$ or $\overline{\text{IRQ}}_0$ Input Combined with General-Purpose Input (Modes 1 to 7)

Table 9-37 Register Read/Write Data

	Read	Write
P7DR	Pin value	Don't care

(5) TXD₂ and TXD₁ Output (P7₄ and P7₂: Modes 1 to 7): Figure 9-48 shows a block diagram illustrating the TXD₂ and TXD₁ output function. Table 9-38 indicates register read/write data. When P7₄ and P7₂ are used for TXD₂ and TXD₁ output, the value written in P7DR is ignored, but P7DR can be read to monitor the levels at the TXD₂ and TXD₁ pins.

Figure 9-48 TXD₂ and TXD₁ Output (Modes 1 to 7)

Table 9-38 Register Read/Write Data

	Read	Write
P7DR	Pin value	Don't care

(6) RXD₂ and RXD₁ Input (P7₅ and P7₃: Modes 1 to 7): Figure 9-49 shows a block diagram illustrating the RXD₂ and RXD₁ input function. Table 9-39 indicates register read/write data. When P7₅ and P7₃ are used for RXD₂ and RXD₁ input, the value written in P7DR is ignored, but P7DR can be read to monitor the levels at the RXD₂ and RXD₁ pins (to detect the line break state, for example).

Figure 9-49 RXD₂ and RXD₁ Input (Modes 1 to 7)

Table 9-39 Register Read/Write Data

9.9 Port 8

9.9.1 Overview

Port 8 is a four-bit input port that is multiplexed with analog input pins of the A/D converter. Figure 9-51 summarizes the pin functions.

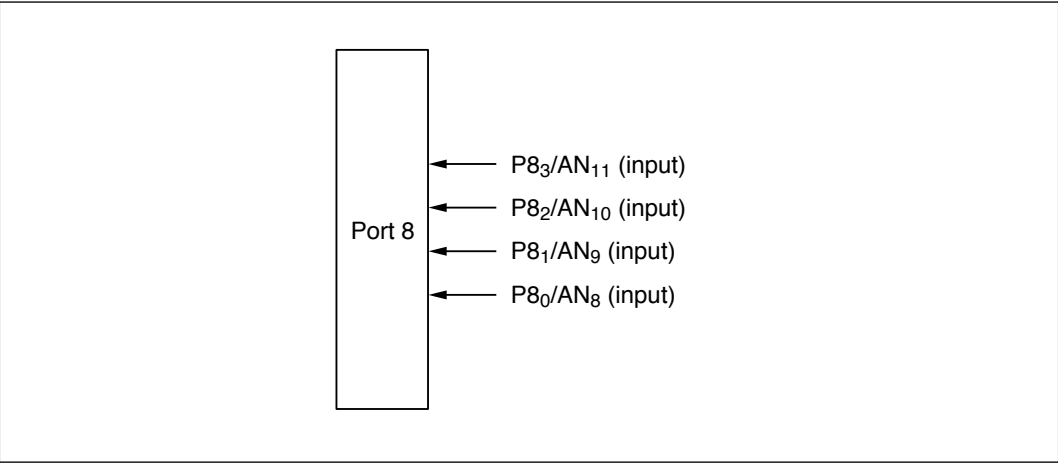

Figure 9-51 Port 8 Pin Functions

9.9.2 Register Descriptions

Table 9-41 summarizes the registers of port 8. Since port 8 is used only for input, there is no data direction register.

Table 9-41 Port 8 Registers

Address	Name	Abbreviation	R/W	Initial Value
H'FE8F	Port 8 data register	P8DR	R	—

(1) Port 8 Data Register: The port 8 data register (P8DR) is an eight-bit register that indicates the values of pins P8₃ to P8₀.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	P8 ₃	P8 ₂	P8 ₁	P8 ₀
Initial value	1	1	1	1	—	—	—	—
R/W	—	—	—	—	R	R	R	R

P8DR is a read-only register. It cannot be written. The upper four bits of P8DR are reserved bits that always return the value 1 when read.

9.9.3 Port 9 Read Operation

Figure 9-52 shows a block diagram of port 8.

While being used for analog input, port 8 can also function as a general-purpose input port. When read, P8DR returns the values at the pins. If P8DR is read when the A/D converter is sampling an analog input, however, the pin being sampled is read as 1.

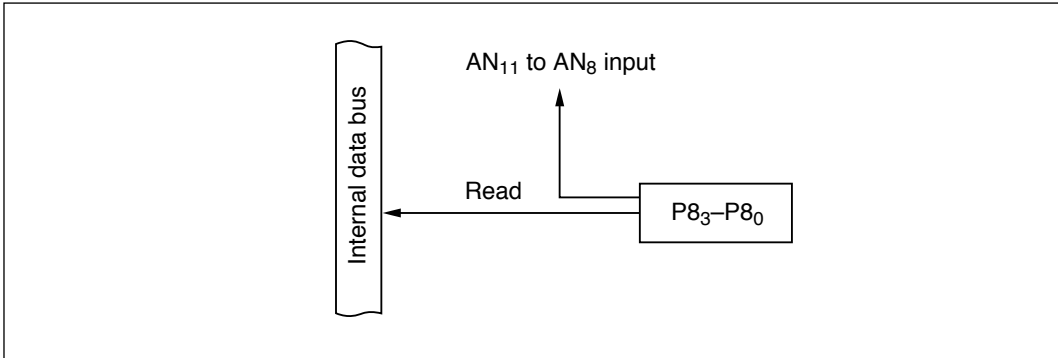

Figure 9-52 Analog Input and General-Purpose Input (Modes 1 to 7)

9.10 Port 9

9.10.1 Overview

Port 9 is an eight-bit input port that is multiplexed with analog input pins of the A/D converter. Figure 9-53 summarizes the pin functions.

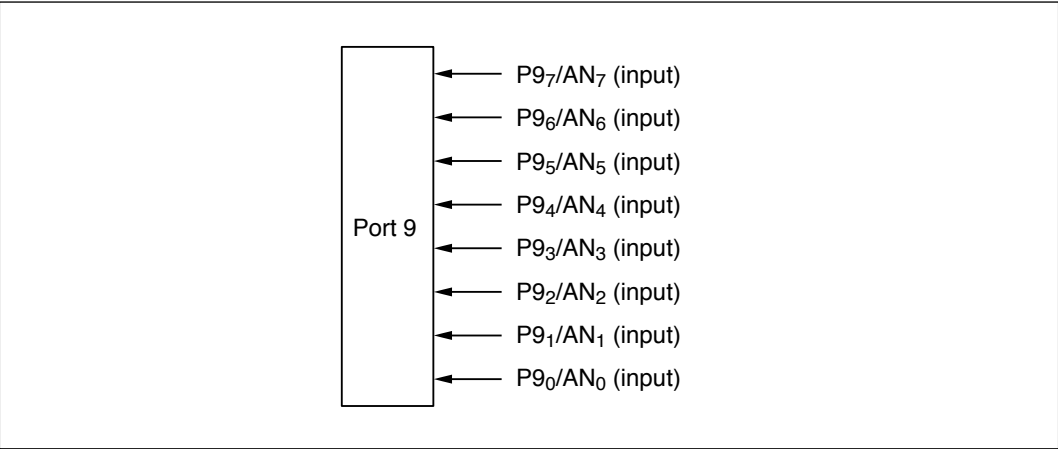

Figure 9-53 Port 9 Pin Functions

9.10.2 Register Descriptions

Table 9-42 summarizes the registers of port 9. Since port 9 is used only for input, there is no data direction register.

Table 9-42 Port 9 Registers

Address	Name	Abbreviation	R/W	Initial Value
H'FE92	Port 9 data register	P9DR	R	—

(1) Port 9 Data Register: The port 9 data register (P9DR) is an eight-bit register that indicates the values of pins P9₇ to P9₀.

Bit	7	6	5	4	3	2	1	0
	P9 ₇	P9 ₆	P9 ₅	P9 ₄	P9 ₃	P9 ₂	P9 ₁	P9 ₀
Initial value	—	—	—	—	—	—	—	—
R/W	R	R	R	R	R	R	R	R

P9DR is a read-only register. It cannot be written.

9.10.3 Port 9 Read Operation

Figure 9-54 shows a block diagram of port 9.

While being used for analog input, port 9 can also function as a general-purpose input port. When read, P9DR returns the values at the pins. If P9DR is read when the A/D converter is sampling an analog input, however, the pin being sampled is read as 1.

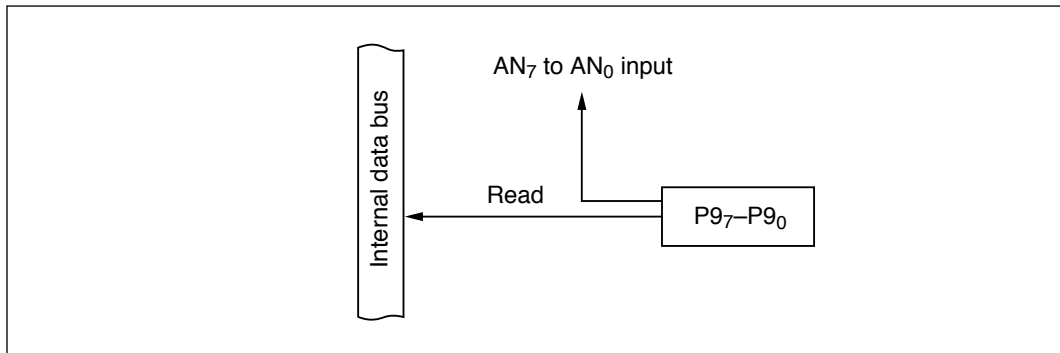

Figure 9-54 Analog Input and General-Purpose Input (Modes 1 to 7)

9.11 Port A

9.11.1 Overview

Port A is a seven-bit input/output port that is multiplexed with output compare pins (T5OC_{2/1}, T4OC_{2/1}, T3OC_{2/1}) of the 16-bit integrated-timer pulse unit (IPU), pins for the $\overline{\text{BREQ}}$, $\overline{\text{BACK}}$, and $\overline{\text{WAIT}}$ signals, and the page address bus (A₁₉ to A₁₆). Figure 9-55 summarizes the pin functions.

Pins in port A can drive one TTL load and a 90-pF capacitive load. They can also drive a Darlington transistor pair.

Figure 9-55 Port A Pin Functions

Figure 9-56 shows examples of output loads for port A.

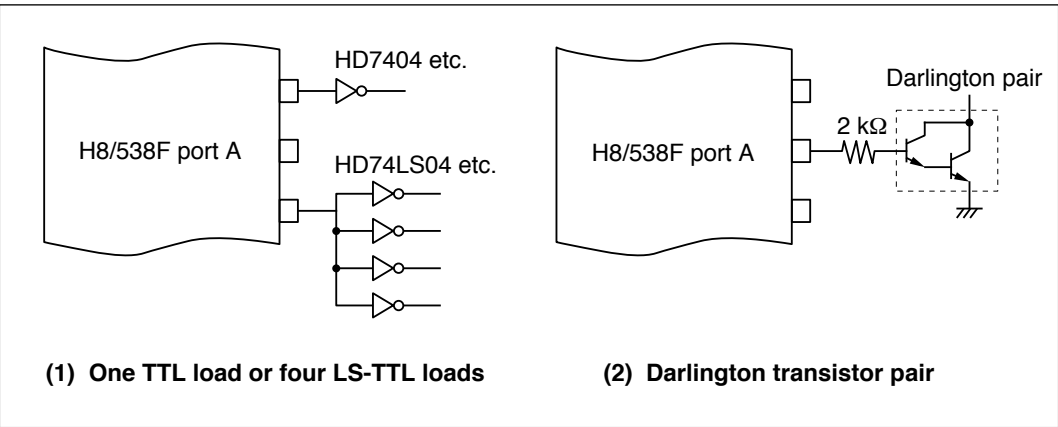

Figure 9-56 Examples of Port A Output Loads

9.11.2 Register Descriptions

Table 9-43 summarizes the registers of port A.

Table 9-43 Port A Registers

Address	Name	Abbreviation	R/W	Initial Value
H'FE91	Port A data direction register	PADDR	W	H'80
H'FE93	Port A data register	PADR	R/W	H'80

(1) Port A Data Direction Register: The port A data direction register (PADDR) is an eight-bit register. Each bit selects input or output for one pin.

Bit	7	6	5	4	3	2	1	0
	—	PA ₆ DDR	PA ₅ DDR	PA ₄ DDR	PA ₃ DDR	PA ₂ DDR	PA ₁ DDR	PA ₀ DDR
Initial value	1	0	0	0	0	0	0	0
R/W	—	W	W	W	W	W	W	W

A pin in port A becomes an output pin if the corresponding PADDR bit is set to 1, and an input pin if this bit is cleared to 0. PADDR is a write-only register. All bits always return the value 1 when read.

PADDR is initialized to H'80 by a reset and in hardware standby mode. PADDR is not initialized in software standby mode.

(2) Port A Data Register: The port A data register (PADR) is an eight-bit register that stores data for pins PA₆ to PA₀.

Bit	7	6	5	4	3	2	1	0
	—	PA ₆	PA ₅	PA ₄	PA ₃	PA ₂	PA ₁	PA ₀
Initial value	1	0	0	0	0	0	0	0
R/W	—	R/W	R/W	R/W	R/W	R/W	R/W	R/W

When a bit in PADDR is set to 1, the corresponding PADR bit value is output at the corresponding pin. If port A is read the value in PADR is returned, regardless of the actual state of the pin.

When a bit in PADDR is cleared to 0, it is possible to write to the corresponding PADR bit but the value is not output at the pin. If PADR is read the value at the pin is returned, regardless of the value written in PADR.

PADR is initialized to H'80 by a reset and in hardware standby mode. PADR is not initialized in software standby mode.

9.11.3 Pin Functions in Each Mode

Port A has different functions in different operating modes. A description for each mode is given next.

(1) Pin Functions in Modes 1, 2, and 6: Port A can be used for the output-compare function ($T3OC_{2/1}$, $T4OC_{2/1}$, $T5OC_{2/1}$) of the 16-bit integrated-timer pulse unit (IPU), bus control (\overline{BREQ} and \overline{BACK}), wait signal input (\overline{WAIT}), and general-purpose output. When a pin is used for output compare, bus control, or wait signal input, the PADDR setting is ignored.

The priority of pin functions for $PA_5/T3OC_1/\overline{BREQ}$ and $PA_6/T3OC_2/\overline{BACK}$ is:

Bus control > output compare > general-purpose output

For methods of selecting pin functions, see appendix D “Pin Function Selection.”

Figure 9-57 shows the functions of port A in modes 1, 2, and 6.

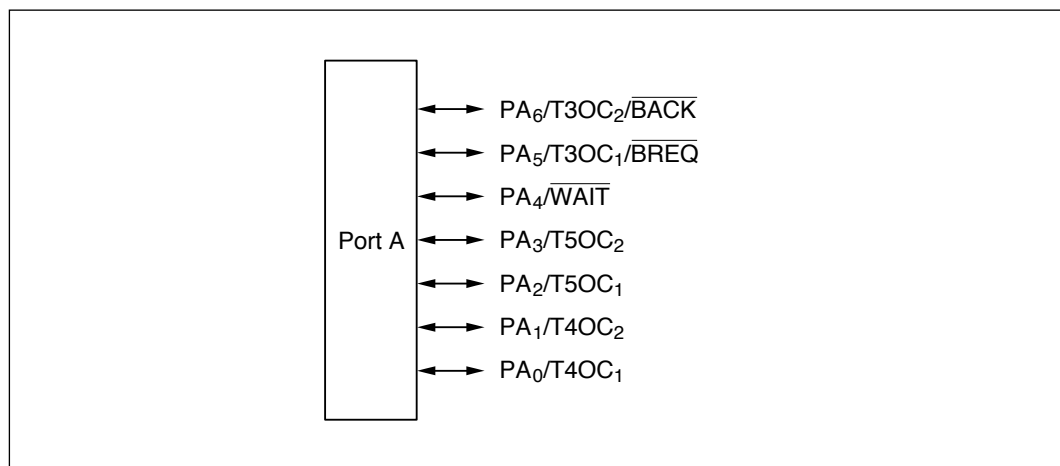

Figure 9-57 Port A Pin Functions in Modes 1, 2, and 6

(2) Pin Functions in Modes 3 and 5: Port A has pins that can be used for the output compare function ($T3OC_{2/1}$) of the 16-bit integrated-timer pulse unit (IPU), bus control (\overline{BREQ} and \overline{BACK}), wait signal input (\overline{WAIT}), or general-purpose input or output, and pins that are used for page address output (A_{19} to A_{16}). When a pin is used for output compare, bus control, or wait signal input, the PADDR setting is ignored.

The priority of pin functions for $PA_5/T3OC_1/\overline{BREQ}$ and $PA_6/T3OC_2/\overline{BACK}$ is:

Bus control > output compare > general-purpose output

For methods of selecting pin functions, see appendix D “Pin Function Selection.”

Figure 9-58 shows the functions of port A in modes 3 and 5.

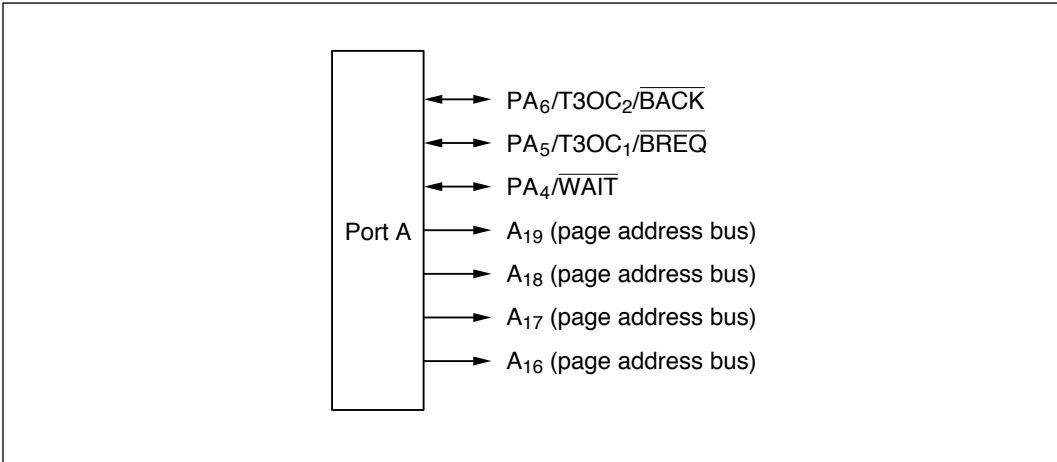

Figure 9-58 Port A Pin Functions in Modes 3 and 5

(3) Pin Functions in Mode 4: Port A has pins that can be used for the output compare function ($T3OC_{2/1}$) of the 16-bit integrated-timer pulse unit (IPU), bus control (\overline{BREQ} and \overline{BACK}), wait signal input (\overline{WAIT}), or general-purpose input or output, and pins that can be used for page address output (A_{19} to A_{16}) or general-purpose input. When a pin is used for output compare, bus control, or wait signal input, the PADDR setting is ignored. Pins PA_3 to PA_0 are used for page address output if the corresponding PADDR bit is set to 1, and for general-purpose input if this bit is cleared to 0.

The priority of pin functions for $PA_5/T3OC_1/\overline{BREQ}$ and $PA_6/T3OC_2/\overline{BACK}$ is:

Bus control > output compare > general-purpose output

For methods of selecting pin functions, see appendix D “Pin Function Selection.”

Figure 9-59 shows the functions of port A in mode 4.

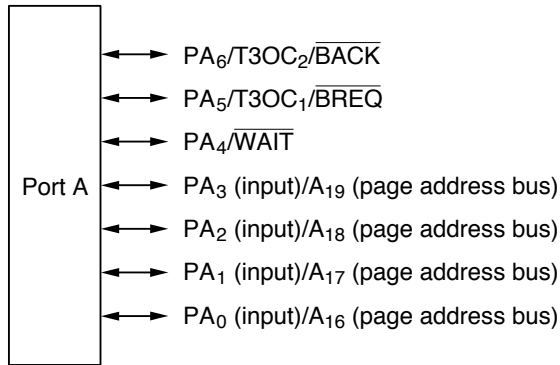

Figure 9-59 Port A Pin Functions in Mode 4

(4) Pin Functions in Mode 7: Port A can be used for the output compare function (T3OC_{2/1}, T4OC_{2/1}, T5OC_{2/1}) of the 16-bit integrated-timer pulse unit (IPU), and general-purpose input or output. When a pin is used for output compare, the PADDR setting is ignored.

For methods of selecting pin functions, see appendix D “Pin Function Selection.”

Figure 9-60 shows the functions of port A in mode 7.

Figure 9-60 Port A Pin Functions in Mode 7

9.11.4 Port A Read/Write Operations

PADR and PADDR have different read/write functions depending on whether port A is used for bus control ($\overline{\text{BREQ}}$, $\overline{\text{BACK}}$), wait signal input ($\overline{\text{WAIT}}$), the output compare function ($\text{T5OC}_{2/1}$, $\text{T4OC}_{2/1}$, $\text{T3OC}_{2/1}$) of the 16-bit integrated-timer pulse unit (IPU), or general-purpose input or output. The operating states and functions of port A are described next.

(1) Input Port (PA_6 to PA_4 in Modes 1 to 7; PA_3 to PA_0 in Modes 1, 2, 4, 6, and 7): Figure 9-61 shows a block diagram illustrating the general-purpose input function. Table 9-44 indicates register read/write data. Values written in the port A data register (PADR) have no effect on general-purpose input lines. When read, PADR returns the value at the pin.

Figure 9-61 Input Port (Modes 1 to 7)

Table 9-44 Register Read/Write Data

	Read	Write
PADR	Pin value	Don't care

(2) **Output Port (PA₆ to PA₄ in Modes 1 to 7; PA₃ to PA₀ in Modes 1, 2, 6, and 7):** Figure 9-62 shows a block diagram illustrating the general-purpose output function. Table 9-45 indicates register read/write data. The value written in the port A data register (PADR) is output at the pin. When read, PADR returns the value written in PADR.

Figure 9-62 Output Port (Modes 1 to 7)

Table 9-45 Register Read/Write Data

	Read	Write
PADR	PADR value	Don't care

(3) **BREQ Pin (PA₅; Modes 1 to 6):** Figure 9-63 shows a block diagram illustrating the BREQ function. Table 9-46 indicates register read/write data. When PA₅ is used for BREQ input, the value written in the port A data register (PADR) has no effect. When read, PADR returns the level of the BREQ signal.

Figure 9-63 BREQ Input Pin (Modes 1 to 6)

Table 9-46 Register Read/Write Data

	Read	Write
PADR	Pin value	Don't care

(4) **$\overline{\text{BACK}}$ Pin (PA_6 : Modes 1 to 6):** Figure 9-64 shows a block diagram illustrating the $\overline{\text{BACK}}$ function. Table 9-47 indicates register read/write data. When PA_6 is used for $\overline{\text{BACK}}$ output, the value written in the port A data register (PADR) has no effect. When read, PADR returns the level of the $\overline{\text{BACK}}$ signal.

Figure 9-64 $\overline{\text{BACK}}$ Output Pin (Modes 1 to 6)

Table 9-47 Register Read/Write Data

	Read	Write
PADR	Pin value	Don't care

(5) $\overline{\text{WAIT}}$ Pin (PA_4 ; Modes 1 to 6): Figure 9-65 shows a block diagram illustrating the $\overline{\text{WAIT}}$ function. Table 9-48 indicates register read/write data. When PA_6 is used for $\overline{\text{WAIT}}$ input, the value written in the port A data register (PADR) has no effect. When read, PADR returns the level of the $\overline{\text{WAIT}}$ signal.

Figure 9-65 $\overline{\text{WAIT}}$ Input Pin (Modes 1 to 6)

Table 9-48 Register Read/Write Data

	Read	Write
PADR	Pin value	Don't care

(6) Timer Output Pins (PA_6 , PA_5 , PA_3 to PA_0 ; Modes 1 to 7): Figure 9-66 shows a block diagram illustrating the timer output function. Table 9-49 indicates register read/write data. When PA_6 , PA_5 , and PA_3 to PA_0 are used for T3OC_2 , T3OC_1 , T5OC_2 , T5OC_1 , T4OC_2 , and T4OC_1 output, values written in the port A data register (PADR) have no effect on the timer output. PADR can be read to monitor the timer output level (T3OC_2 , T3OC_1 , T5OC_2 , T5OC_1 , T4OC_2 , T4OC_1).

Figure 9-66 Output Compare Pins (Modes 1 to 7)

Table 9-49 Register Read/Write Data

	Read	Write
PADR	Pin value	Don't care

(7) Page Address Bus (PA₃ to PA₀: Modes 3 to 5): Figure 9-67 shows a block diagram illustrating the page-address-bus function. Table 9-50 indicates register read/write data. When PA₃ to PA₀ are used for A₁₉ to A₁₆ output, values written in the port A data register (PADR) have no effect. When read, PADR returns the value written in PADR.

Figure 9-67 Page Address Bus (Modes 3 to 5)

Table 9-50 Register Read/Write Data

	Read	Write
PADR	PADR value	Don't care

9.12 Port B

9.12.1 Overview

Port B is an-eight-bit input/output port. Figure 9-68 summarizes the pin functions.

Port B is an address bus (A_{15} to A_8) in modes 1, 3, 5, and 6. In modes 2 and 4 port B can be used for address output (A_{15} to A_8) or general-purpose input. In mode 7 port B is a general-purpose input/output port.

Pins in port B can drive one TTL load and a 90-pF capacitive load. They can also drive a Darlington transistor pair. They have software-programmable built-in pull-up transistors.

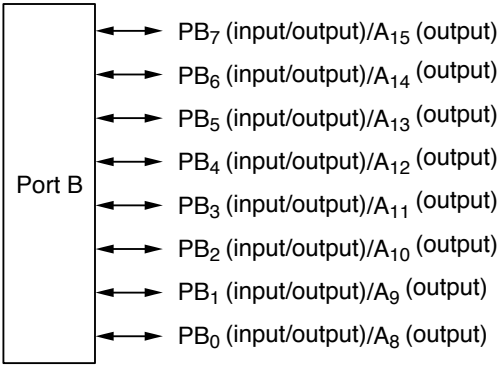

Figure 9-68 Port B Pin Functions

Figure 9-69 shows examples of output loads for port B.

(1) One TTL load or four LS-TTL loads (2) Darlington transistor pair

Figure 9-69 Examples of Port B Output Loads

9.12.2 Register Descriptions

Table 9-51 summarizes the registers of port B.

Table 9-51 Port B Registers

Address	Name	Abbreviation	R/W	Initial Value
H'FE94	Port B data direction register	PBDDR	W	H'00
H'FE96	Port B data register	PBDR	R/W	H'00
H'FE98	Port B pull-up transistor control register	PBPCR	R/W	H'00

(1) Port B Data Direction Register: The port B data direction register (PBDDR) is an-eight-bit register. Each bit selects input or output for one pin.

Bit	7	6	5	4	3	2	1	0
	PB ₇ DDR	PB ₆ DDR	PB ₅ DDR	PB ₄ DDR	PB ₃ DDR	PB ₂ DDR	PB ₁ DDR	PB ₀ DDR
Initial value	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W

A pin in port B becomes an output pin if the corresponding PBDDR bit is set to 1, and an input pin if this bit is cleared to 0. PBDDR is a write-only register. All bits always return the value 1 when read.

PBDDR is initialized to H'00 by a reset and in hardware standby mode. PBDDR is not initialized in software standby mode.

(2) Port B Data Register: The port B data register (PBDR) is an-eight-bit register that stores data for pins PB₇ to PB₀.

Bit	7	6	5	4	3	2	1	0
	PB ₇	PB ₆	PB ₅	PB ₄	PB ₃	PB ₂	PB ₁	PB ₀
Initial value	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

When a bit in PBDDR is set to 1, the corresponding PBDR bit value is output at the corresponding pin. If port B is read the value in PBDR is returned, regardless of the actual state of the pin.

When a bit in PBDDR is cleared to 0, it is possible to write to the corresponding PBDR bit but the

value is not output at the pin. If PBDR is read the value at the pin is returned, regardless of the value written in PBDR.

PBDR is initialized to H'00 by a reset and in hardware standby mode. PBDR is not initialized in software standby mode.

(3) Port B Pull-Up Transistor Control Register: The port B pull-up transistor control register (PBPCR) is an-eight-bit register that turns the MOS pull-up transistors of PB₇ to PB₀ on and off. PBPCR is ignored in modes 1 to 6 and used only in mode 7.

Bit	7	6	5	4	3	2	1	0
	PB ₇ PON	PB ₆ PON	PB ₅ PON	PB ₄ PON	PB ₃ PON	PB ₂ PON	PB ₁ PON	PB ₀ PON
Initial value	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

When a PBDDR bit is cleared to 0, if the corresponding PBPCR bit is set to 1, the built-in pull-up transistor is turned on.

PBPCR is initialized to H'00 by a reset and in hardware standby mode. PBPCR is not initialized in software standby mode.

9.12.3 Pin Functions in Each Mode

Port B has one set of functions in modes 1, 3, 5, and 6, another set of functions in modes 2 and 4, and another set of functions in mode 7. A description for each mode group is given next.

(1) Pin Functions in Modes 1, 3, 5, and 6: Port B is used for address output (A₁₅ to A₈). The PBDDR settings are ignored. Figure 9-70 shows the pin functions in modes 1, 3, 5, and 6.

Figure 9-70 Pin Functions in Modes 1, 3, 5, and 6

(2) Pin Functions in Modes 2 and 4: Port B can be used for address output (A_{15} to A_8) or general-purpose input. A pin is used for address output if the corresponding PBDDR bit is set to 1, and for general-purpose input if this bit is cleared to 0. Figure 9-71 shows the pin functions in modes 2 and 4.

Figure 9-71 Pin Functions in Modes 2 and 4

(3) Pin Functions in Mode 7: Port B consists of general-purpose input/output pins. Input or output can be selected separately for each pin. A pin becomes an output pin if the corresponding PBDDR bit is set to 1 and an input pin if this bit is cleared to 0. Figure 9-72 shows the pin functions in mode 7.

Figure 9-72 Pin Functions in Mode 7

9.12.4 Built-In Pull-Up Transistors

Port B has built-in MOS pull-up transistors that can be controlled by software. To turn an input pull-up transistor on, clear its PBDDR bit to 0 and set its PBPCR bit to 1. The input pull-up transistors are turned off by a reset and in hardware standby mode. Table 9-52 summarizes the states of the input pull-ups in each mode.

Table 9-52 Pull-Up Transistor States in Each Mode

Mode	Reset	Hardware Standby Mode	Other Modes (including software standby mode)
1–6	Off	Off	Off
7			On/Off

9.12.5 Port B Read/Write Operations

PBDR and PBDDR have different read/write functions depending on whether port B is used for address output (A_{15} to A_8) or general-purpose input or output. The operating states and functions of port B are described next.

(1) Input Port (all pins: Modes 2 and 4): Figure 9-73 shows a block diagram illustrating the general-purpose input function. Table 9-53 indicates register read/write data. Values written in the port B data register (PBDR) have no effect on general-purpose input lines. When read, PBDR returns the value at the pin.

Figure 9-73 Input Port (Modes 2 and 4)

Table 9-53 Register Read/Write Data

	Read	Write
PBDR	Pin value	Don't care

(2) Input Port with Internal Pull-Up (All Pins: Mode 7): Figure 9-74 shows a block diagram illustrating the general-purpose input function and built-in input pull-up transistors. Table 9-54 indicates register read/write data. Values written in the port B data register (PBDR) have no effect on general-purpose input lines. When read, PBDR returns the value at the pin. When a bit in the port B pull-up transistor control register (PBPCR) is set to 1, the corresponding PBDR bit always reads 1.

Figure 9-74 Input Port with Built-In Pull-Up Transistors (Mode 7)

Table 9-54 Register Read/Write Data

	Read	Write
PBDR	Pin value, or always 1*	Don't care
PBPCR	PBPCR value	0/1*

Note: * If a PBPCR bit is set to 1, the corresponding PBDR bit always reads 1.

(3) Output Port (All Pins: Mode 7): Figure 9-75 shows a block diagram illustrating the general-purpose output function. Table 9-55 indicates register read/write data. The value written in the port B data register (PBDR) is output at the pin. When read, PBDR returns the value written in PBDR.

Figure 9-75 Output Port (Mode 7)

Table 9-55 Register Read/Write Data

	Read	Write
PBDR	PBDR value	Value output at pin

(4) Address Bus (All Pins: Modes 1 to 6): Figure 9-76 shows a block diagram illustrating the address-bus function. Table 9-56 indicates register read/write data. When port B is used as an address bus, values written in the port B data register (PBDR) have no effect on the bus lines. When read, PBDR returns the value written in PBDR.

Figure 9-76 Address Bus (Modes 1 to 6)

Table 9-56 Register Read/Write Data

	Read	Write
PBDR	PBDR value	Don't care

9.13 Port C

9.13.1 Overview

Port C is an eight-bit input/output port. Figure 9-77 summarizes the pin functions.

Port C is an address bus (A_7 to A_0) in modes 1, 3, 5, and 6. In modes 2 and 4 port C can be used for address output (A_7 to A_0) or general-purpose input. In mode 7 port C is a general-purpose input/output port.

Pins in port C can drive one TTL load and a 90-pF capacitive load. They can also drive a Darlington transistor pair. They have software-programmable built-in pull-up transistors.

Figure 9-77 Port C Pin Functions

Figure 9-78 shows examples of output loads for port C.

(1) One TTL load or four LS-TTL loads

(2) Darlington transistor pair

Figure 9-78 Examples of Port C Output Loads

9.13.2 Register Descriptions

Table 9-57 summarizes the registers of port C.

Table 9-57 Port C Registers

Address	Name	Abbreviation	R/W	Initial Value
H'FE95	Port C data direction register	PCDDR	W	H'00
H'FE97	Port C data register	PCDR	R/W	H'00
H'FE99	Port C pull-up transistor control register	PCPCR	R/W	H'00

(1) Port C Data Direction Register: The port C data direction register (PCDDR) is an-eight-bit register. Each bit selects input or output for one pin.

Bit	7	6	5	4	3	2	1	0
	PC ₇ DDR	PC ₆ DDR	PC ₅ DDR	PC ₄ DDR	PC ₃ DDR	PC ₂ DDR	PC ₁ DDR	PC ₀ DDR
Initial value	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W

A pin in port C becomes an output pin if the corresponding PCDDR bit is set to 1, and an input pin if this bit is cleared to 0. PCDDR is a write-only register. All bits always return the value 1 when read.

PCDDR is initialized to H'00 by a reset and in hardware standby mode. PCDDR is not initialized in software standby mode.

(2) Port C Data Register: The port C data register (PCDR) is an-eight-bit register that stores data for pins PC₇ to PC₀.

Bit	7	6	5	4	3	2	1	0
	PC ₇	PC ₆	PC ₅	PC ₄	PC ₃	PC ₂	PC ₁	PC ₀
Initial value	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

When a bit in PCDDR is set to 1, the corresponding PCDR bit value is output at the corresponding pin. If port C is read the value in PCDR is returned, regardless of the actual state of the pin.

When a bit in PCDDR is cleared to 0, it is possible to write to the corresponding PCDR bit but the

value is not output at the pin. If PCDR is read the value at the pin is returned, regardless of the value written in PCDR.

PCDR is initialized to H'00 by a reset and in hardware standby mode. PCDR is not initialized in software standby mode.

(3) Port C Pull-Up Transistor Control Register: The port C pull-up transistor control register (PCPCR) is an-eight-bit register that turns the MOS pull-up transistors of PC₇ to PC₀ on and off. PCPCR is ignored in modes 1 to 6 and used only in mode 7.

Bit	7	6	5	4	3	2	1	0
	PC ₇ PON	PC ₆ PON	PC ₅ PON	PC ₄ PON	PC ₃ PON	PC ₂ PON	PC ₁ PON	PC ₀ PON
Initial value	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

When a PCDDR bit is cleared to 0, if the corresponding PCPCR bit is set to 1, the built-in pull-up transistor is turned on.

PCPCR is initialized to H'00 by a reset and in hardware standby mode. PCPCR is not initialized in software standby mode.

9.13.3 Pin Functions in Each Mode

Port C has one set of functions in modes 1, 3, 5, and 6, another set of functions in modes 2 and 4, and another set of functions in mode 7. A description for each mode group is given next.

(1) Pin Functions in Modes 1, 3, 5, and 6: Port C is used for address output (A₇ to A₀). The PCDDR settings are ignored. Figure 9-79 shows the pin functions in modes 1, 3, 5, and 6.

Figure 9-79 Pin Functions in Modes 1, 3, 5, and 6

(2) Pin Functions in Modes 2 and 4: Port C can be used for address output (A₇ to A₀) or general-purpose input. A pin is used for address output if the corresponding PCDDR bit is set to 1, and for general-purpose input if this bit is cleared to 0. Figure 9-80 shows the pin functions in modes 2 and 4.

Figure 9-80 Pin Functions in Modes 2 and 4

(3) Pin Functions in Mode 7: Port C consists of general-purpose input/output pins. Input or output can be selected separately for each pin. A pin becomes an output pin if the corresponding PCDDR bit is set to 1 and an input pin if this bit is cleared to 0. Figure 9-81 shows the pin functions in mode 7.

Figure 9-81 Pin Functions in Mode 7

9.13.4 Built-In MOS Pull-Up Transistors

Port C has built-in MOS pull-up transistors that can be controlled by software. To turn an input pull-up transistor on, clear its PCDDR bit to 0 and set its PCPCR bit to 1. The input pull-up transistors are turned off by a reset and in hardware standby mode. Table 9-58 summarizes the states of the input pull-ups in each mode.

Table 9-58 Pull-Up Transistor States in Each Mode

Mode	Reset	Hardware Standby Mode	Other Modes (Including Software Standby Mode)
1–6	Off	Off	Off
7			On/Off

9.13.5 Port C Read/Write Operations

PCDR and PCDDR have different read/write functions depending on whether port C is used for address output (A_7 to A_0) or general-purpose input or output. The operating states and functions of port C are described next.

(1) Input Port (All pins: Modes 2 and 4): Figure 9-82 shows a block diagram illustrating the general-purpose input function. Table 9-59 indicates register read/write data. Values written in the port C data register (PCDR) have no effect on general-purpose input lines. When read, PCDR returns the value at the pin.

Figure 9-82 Input Port (Modes 2 and 4)

Table 9-59 Register Read/Write Data

	Read	Write
PCDR	Pin value	Don't care

(2) Input Port with Internal Pull-Up (All Pins: Mode 7): Figure 9-83 shows a block diagram illustrating the general-purpose input function of port C using the built-in input pull-up transistors. Table 9-60 indicates register read/write data. Values written in the port C data register (PCDR) have no effect on general-purpose input lines. When read, PCDR returns the value at the pin. When a bit in the port C pull-up transistor control register (PCPCR) is set to 1, the corresponding PCDR bit always reads 1.

Figure 9-83 Input Port with Built-In Pull-Up Transistors (Mode 7)

Table 9-60 Register Read/Write Data

	Read	Write
PCDR	Pin value, or always 1*	Don't care
PCPCR	PCPCR value	0/1*

Note: * If a PCPCR bit is set to 1, the corresponding PCDR bit always reads 1.

(3) Output Port (All Pins: Mode 7): Figure 9-84 shows a block diagram illustrating the general-purpose output function. Table 9-61 indicates register read/write data. The value written in the port C data register (PCDR) is output at the pin. When read, PCDR returns the value written in PCDR.

Figure 9-84 Output Port (Mode 7)

Table 9-61 Register Read/Write Data

	Read	Write
PCDR	PCDR value	Value output at pin

(4) Address Bus (All Pins: Modes 1 to 6): Figure 9-85 shows a block diagram illustrating the address-bus function. Table 9-62 indicates register read/write data. When port C is used as an address bus, values written in the port C data register (PCDR) have no effect on the bus lines. When read, PCDR returns the value written in PCDR.

Figure 9-85 Address Bus (Modes 1 to 6)

Table 9-62 Register Read/Write Data

	Read	Write
PCDR	PCDR value	Don't care

Section 10 16-Bit Integrated-Timer Pulse Unit

10.1 Overview

The H8/538F has a built-in 16-bit integrated-timer pulse unit (IPU) with seven channels and three types of timers. The IPU can output 28 independent waveforms, or output 12 waveforms and process 16 pulse inputs or outputs. It can also provide multi-phase PWM output, automatically measure pulse widths and periods, count input from a two-phase encoder, and start the A/D converter.

10.1.1 Features

The IPU features are listed below.

- Twelve waveform outputs and sixteen pulse inputs or outputs
- Sixteen registers with software-assignable output compare or input capture functions
- Twenty-eight independent comparators

Channel	Output Compare Registers	Output Compare/Input Capture Registers
CH1	4	4
CH2–5	2	2
CH6, 7	—	2

- Selection of sixteen counter clock sources (external clock sources are shared by all channels):
 ϕ , $\phi/2$, $\phi/4$, $\phi/8$, $\phi/16$, $\phi/32$, $\phi/64$, $\phi/128$, $\phi/256$, $\phi/512$, $\phi/1024$, $\phi/2048$, $\phi/4096$, TCLK1, TCLK2, TCLK3
- Input capture function
Rising edge, falling edge, or both edges
- Pulse output
One-shot, toggle, or PWM output
- Counter synchronization function

Software can write to two or more timer counters simultaneously. Counters can be cleared simultaneously by compare match or input capture.

- PWM output mode

One-phase, two-phase, or three-phase PWM output (up to nine-phase PWM output using the counter synchronization function)

- Auto-measure function

Two timer channels can be coordinated for automatic measurement of pulse width or frequency and for two-phase encoder counting

- Thirty-five interrupt sources

16 compare match/input capture interrupts, 12 compare match interrupts, and 7 overflow interrupts: total 35 sources. The compare match/input capture interrupts and overflow interrupts are independently vectored. The compare match interrupts have one interrupt vector per two interrupt sources. The compare match/input capture interrupts and compare match interrupts can start the data transfer controller (DTC) to transfer data.

10.1.2 Block Diagram

Figure 10-1 shows a block diagram of the IPU.

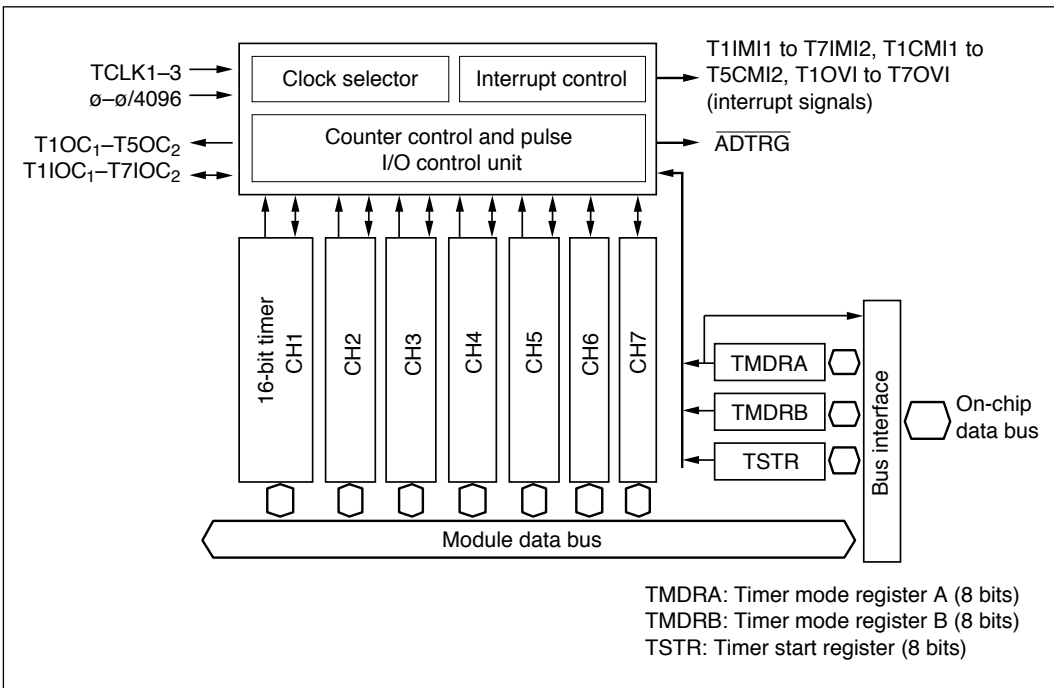

Figure 10-1 IPU Block Diagram

10.1.3 Input/Output Pins

Table 10-1 summarizes the IPU pins.

Table 10-1 IPU Pins

Channel	Pin Name	Input/Output	Function
1	T1IOC ₁	Input/Output	T1GR1 output compare/input capture pin (multiplexed with PWM output)
	T1IOC ₂	Input/Output	T1GR2 output compare/input capture pin (multiplexed with PWM output)
	T1OC ₁	Output	T1DR1 output compare pin (multiplexed with PWM output)
	T1OC ₂	Output	T1DR2 output compare pin
	T1IOC ₃	Input/Output	T1GR3 output compare/input capture pin
	T1IOC ₄	Input/Output	T1GR4 output compare/input capture pin
	T1OC ₃	Output	T1DR3 output compare pin
	T1OC ₄	Output	T1DR4 output compare pin
2	T2IOC ₁	Input/Output	T2GR1 output compare/input capture pin (multiplexed with PWM output)
	T2IOC ₂	Input/Output	T2GR2 output compare/input capture pin (multiplexed with PWM output)
	T2OC ₁	Output	T2DR1 output compare pin
	T2OC ₂	Output	T2DR2 output compare pin
3	T3IOC ₁	Input/Output	T3GR1 output compare/input capture pin (multiplexed with PWM output)
	T3IOC ₂	Input/Output	T3GR2 output compare/input capture pin (multiplexed with PWM output)
	T3OC ₁	Output	T3DR1 output compare pin
	T3OC ₂	Output	T3DR2 output compare pin
4	T4IOC ₁	Input/Output	T4GR1 output compare/input capture pin
	T4IOC ₂	Input/Output	T4GR2 output compare/input capture pin
	T4OC ₁	Output	T4DR1 output compare pin
	T4OC ₂	Output	T4DR2 output compare pin

Table 10-1 IPU Pins (cont)

Channel	Pin Name	Input/Output	Function
5	T5IOC ₁	Input/Output	T5GR1 output compare/input capture pin
	T5IOC ₂	Input/Output	T5GR2 output compare/input capture pin
	T5OC ₁	Output	T5DR1 output compare pin
	T5OC ₂	Output	T5DR2 output compare pin
6	T6IOC ₁	Input/Output	T6GR1 output compare/input capture pin (multiplexed with PWM output)
	T6IOC ₂	Input/Output	T6GR2 output compare/input capture pin
7	T7IOC ₁	Input/Output	T7GR1 output compare input capture pin (multiplexed with PWM output)
	T7IOC ₂	Input/Output	T7GR2 output compare input capture pin
External clock	TCLK ₁	Input	External clock 1 input pin (A phase input for phase measurement mode)
	TCLK ₂	Input	External clock 2 input pin (B phase input for phase measurement mode)
	TCLK ₃	Input	External clock 3

10.2 Timer Counters and Compare/Capture Registers

The IPU has seven 16-bit timer counters (TCNTs), one for each channel. Each counter can be accessed 16 bits at a time.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TCNT																
Initial value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Each of the seven channels has 16-bit capture and compare registers. A capture register latches the TCNT value when an external capture signal is received or an event occurs. Compare register contents are compared with the TCNT value at all times, and a compare match signal and/or interrupt is generated when the two match. The configuration of each channel will be described next.

10.3 Channel 1 Registers

Channel 1 has four general registers used for both input capture and output compare, and four dedicated registers used only for output compare.

The input capture/output compare registers function as output compare registers after a reset. They can be switched over to input capture by setting bits IEG41 to IEG10 in the timer control registers.

Channel 1 can simultaneously generate a maximum of eight waveforms, or can simultaneously generate four waveforms and measure four waveforms. Three-phase PWM output is possible in PWM mode. See section 10.8, “Examples of Timer Operation” for details.

Figure 10-2 shows a block diagram of channel 1.

Figure 10-2 Channel 1 Block Diagram

10.3.1 Register Configuration

Table 10-2 summarizes the channel 1 registers.

Table 10-2 Channel 1 Registers

Channel	Address	Name	Abbreviation	R/W	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0	Initial Value

10.3.2 Timer Control Register (High)

Timer control register high (TCRH) is an eight-bit readable/writable register that selects the timer clock source. Each channel has one TCRH. The bit structure of TCRH in channel 1 is shown next.

Bit	7	6	5	4	3	2	1	0
TCRH	—	—	CKEG1	CKEG0	TPSC3	TPSC2	TPSC1	TPSC0
Initial value	1	1	0	0	0	0	0	0
R/W	—	—	R/W	R/W	R/W	R/W	R/W	R/W

Reserved bits

Clock edge 1/0
These bits select the external clock edge

Timer prescaler 3–0
These bits select the clock source

- (1) **Bits 7 and 6—Reserved:** Read-only bits, always read as 1.
- (2) **Bits 5 and 4—Clock Edge 1/0 (CKEG1/0):** These bits select the external clock edge.

Bit 5	Bit 4	Description
CKEG1	CKEG0	
0	0	Increment on rising edge (Initial value)
0	1	Increment on falling edge
1	0	Increment on both edges
1	1	

CKEG1/0 can be set to increment the count on the rising edge, falling edge, or both edges of the external clock. When TPSC3 to TPSC0 are set so as not to select an external clock source, CKEG1 and CKEG0 are ignored.

For further details, see section 10.8.7, “External Event Counting.”

(3) Bits 3 to 0—Timer Prescaler (TPSC3 to TPSC0): These bits select the clock source. One of 16 clock sources can be selected, as listed next.

Bit 3	Bit 2	Bit 1	Bit 0			
TPSC3	TPSC2	TPSC1	TPSC0	Description		
0	0	0	0	\varnothing	(100 ns)*	(Initial value)
0	0	0	1	$\varnothing/2$	(200 ns)*	
0	0	1	0	$\varnothing/4$	(400 ns)*	
0	0	1	1	$\varnothing/8$	(800 ns)*	
0	1	0	0	$\varnothing/16$	(1.6 μ s)*	
0	1	0	1	$\varnothing/32$	(3.2 μ s)*	
0	1	1	0	$\varnothing/64$	(6.4 μ s)*	
0	1	1	1	$\varnothing/128$	(12.8 μ s)*	
1	0	0	0	$\varnothing/256$	(25.6 μ s)*	
1	0	0	1	$\varnothing/512$	(51.2 μ s)*	
1	0	1	0	$\varnothing/1024$	(102.4 μ s)*	
1	0	1	1	$\varnothing/2048$	(204.8 μ s)*	
1	1	0	0	$\varnothing/4096$	(409.6 μ s)*	
1	1	0	1	External clock (TCLK ₁)		
1	1	1	0	External clock (TCLK ₂)		
1	1	1	1	External clock (TCLK ₃)		

Note: * Values in parentheses are resolution values for a 10-MHz clock rate.

10.3.3 Timer Control Register (Low)

Timer control register low (TCRL) is an eight-bit readable/writable register that selects register functions and input capture edges, and selects the timer counter clear source.

Channel 1 has two timer control registers (low), designated TCRL and TCRA. The bit structure of TCRL in channel 1 is shown next.

Bit	7	6	5	4	3	2	1	0
TCRL	—	CCLR2	CCLR1	CCLR0	IEG21	IEG20	IEG11	IEG10
Initial value	1	0	0	0	0	0	0	0
R/W	—	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Input capture edge 21/20/11/10
These bits select register functions and the valid edges of input capture signals

Counter clear 2–0
These bits select the counter clear source

Reserved bit

(1) **Bit 7 —Reserved:** Read-only bit, always read as 1.

(2) Bits 6 to 4—Counter Clear 2 to 0 (CCLR2/1/0): These bits select the counter clear source.

Bit 6	Bit 5	Bit 4	Description
CCLR2	CCLR1	CCLR0	
0	0	0	Counter not cleared (Initial value)
0	0	1	Synchronized counter clearing enabled
0	1	0	
0	1	1	
1	0	0	Counter cleared on GR1 compare match or capture
1	0	1	Counter cleared on DR2 compare match
1	1	0	Counter cleared on GR3 compare match or capture
1	1	1	Counter cleared on DR4 compare match

When CCLR2 is 0 and either CCLR1 or CCLR0 is set to 1, or both CCLR1 and CCLR0 are set to 1, the counter is cleared in synchronization with the clearing of a timer pair selected in timer mode register A (TMDA).

If GR1 or GR3 is used as a compare register the counter is cleared by compare match. If GR1 or GR3 is used as a capture register the counter is cleared by input capture.

For further details, see section 10.8.4, “Counter Clearing Function” and section 10.8.6, “Synchronizing Mode.”

(3) Bits 3 and 2—Input Capture Edge 21/20 (IEG21/20): These bits select the function of GR2 and the valid edge of the input capture signal.

Bit 3	Bit 2	Description
IEG21	IEG20	
0	0	GR2 is not used for input capture (Initial value)*
0	1	GR2 captures rising edge of input capture signal
1	0	GR2 captures falling edge of input capture signal
1	1	GR2 captures both edges of input capture signal

Note: * GR2 becomes an output compare register.

A reset clears bits IEG21 and IEG20 to 0, disabling input capture and making GR2 an output compare register. If IEG21 or IEG20 is set to 1, or both IEG21 and IEG20 are set to 1, GR2 becomes an input capture register.

For further details, see section 10.8.3, “Input Capture Function.”

(4) Bits 1 and 0—Input Capture Edge 11/10 (IEG11/10): These bits select the function of GR1 and the valid edge of the input capture signal.

Bit 1	Bit 0	
IEG11	IEG10	Description
0	0	GR1 is not used for input capture (Initial value)*
0	1	GR1 captures rising edge of input capture signal
1	0	GR1 captures falling edge of input capture signal
1	1	GR1 captures both edges of input capture signal

Note: * GR1 becomes an output compare register.

A reset clears bits IEG11 and IEG10 to 0, disabling input capture and making GR1 an output compare register. If IEG11 or IEG10 is set to 1, or both IEG11 and IEG10 are set to 1, GR1 becomes an input capture register.

For further details, see section 10.8.3, “Input Capture Function.”

TCRA is an eight-bit readable/writable register. The bit structure of TCRA in channel 1 is shown next.

Bit	7	6	5	4	3	2	1	0
TCRA	—	—	—	—	IEG41	IEG40	IEG31	IEG30
Initial value	1	1	1	1	0	0	0	0
R/W	—	—	—	—	R/W	R/W	R/W	R/W

Reserved bits

Input capture edge 41/40/31/30
 These bits select register functions
 and the valid edges of input capture
 signals

(1) Bits 7 to 4 —Reserved: Read-only bits, always read as 1.

(2) Bits 3 and 2—Input Capture Edge 41/40 (IEG41/40): These bits select the function of GR4 and the valid edge of the input capture signal.

Bit 3	Bit 2	
IEG41	IEG40	Description
0	0	GR4 is not used for input capture (Initial value)*
0	1	GR4 captures rising edge of input capture signal
1	0	GR4 captures falling edge of input capture signal
1	1	GR4 captures both edges of input capture signal

Note: * GR4 becomes an output compare register.

A reset clears bits IEG41 and IEG40 to 0, disabling input capture and making GR4 an output compare register. If IEG41 or IEG40 is set to 1, or both IEG41 and IEG40 are set to 1, GR4 becomes an input capture register.

For further details, see section 10.8.3, “Input Capture Function.”

(3) Bits 1 and 0—Input Capture Edge 31/30 (IEG31/30): These bits select the function of GR3 and the valid edge of the input capture signal.

Bit 1	Bit 0	
IEG31	IEG30	Description
0	0	GR3 is not used for input capture (Initial value)*
0	1	GR3 captures rising edge of input capture signal
1	0	GR3 captures falling edge of input capture signal
1	1	GR3 captures both edges of input capture signal

Note: * GR3 becomes an output compare register.

A reset clears bits IEG31 and IEG30 to 0, disabling input capture and making GR3 an output compare register. If IEG31 or IEG30 is set to 1, or both IEG31 and IEG30 are set to 1, GR3 becomes an input capture register.

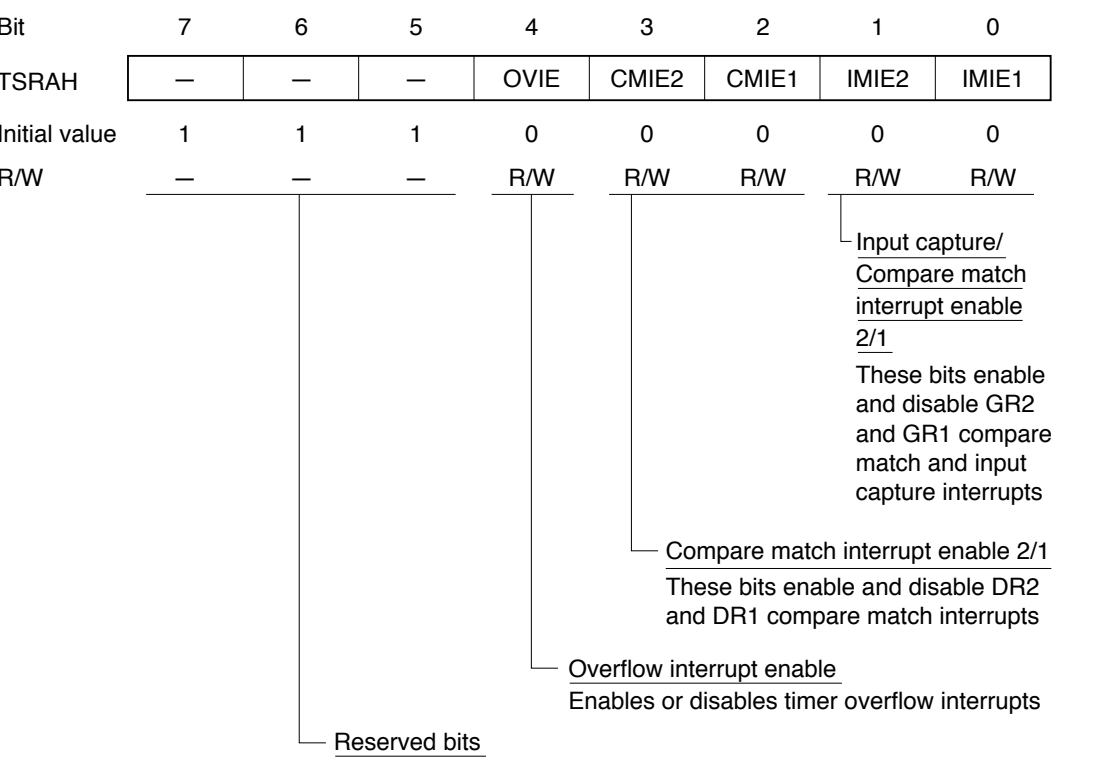

For further details, see section 10.8.3, “Input Capture Function.”

10.3.4 Timer Status Register (High)

Timer status register high (TSRH) is an eight-bit readable/writable register that enables and disables timer interrupts.

After OVIE, CMIE2, CMIE1, IMIE2, or IMIE1 is set to 1 in TSRH, an interrupt is requested when OVF, CMF2, CMF1, IMF2, or IMF1 is set to 1 in TSRL.

Channel 1 has two timer status registers (high), designated TSRAH and TSRBH. Channels 2 to 7 have one TSRH each. The bit structure of TSRAH in channel 1 is shown next.

(1) **Bits 7 to 5—Reserved:** Read-only bits, always read as 1.

(2) Bit 4—Overflow Interrupt Enable (OVIE): Enables or disables the counter overflow interrupt. For further details, see section 10.9.1, “Interrupt Timing.”

Bit 4

OVIE	Description
0	Counter overflow interrupt is disabled (Initial value)
1	Counter overflow interrupt is enabled

(3) Bit 3—Compare Match Interrupt Enable 2 (CMIE2): Enables or disables the DR2 compare match interrupt. For further details, see section 10.9.1, “Interrupt Timing.”

Bit 3

CMIE2	Description
0	DR2 compare match interrupt is disabled (Initial value)
1	DR2 compare match interrupt is enabled

(4) Bit 2—Compare Match Interrupt Enable 1 (CMIE1): Enables or disables the DR1 compare match interrupt. For further details, see section 10.9.1, “Interrupt Timing.”

Bit 2

CMIE1	Description
0	DR1 compare match interrupt is disabled (Initial value)
1	DR1 compare match interrupt is enabled

(5) Bit 1—Input Capture/Compare Match Interrupt Enable 2 (IMIE2): Enables or disables the GR2 compare match or input capture interrupt. For further details, see section 10.9.1, “Interrupt Timing.”

Bit 1

IMIE2	Description
0	GR2 compare match or input capture interrupt is disabled (Initial value)
1	GR2 compare match or input capture interrupt is enabled

(6) Bit 0—Input Capture/Compare Match Interrupt Enable 1 (IMIE1): Enables or disables the GR1 compare match or input capture interrupt. For further details, see section 10.9.1, “Interrupt Timing.”

Bit 0		
IMIE1	Description	
0	GR1 compare match or input capture interrupt is disabled	(Initial value)
1	GR1 compare match or input capture interrupt is enabled	

TSRBH is an eight-bit readable/writable register. The bit structure of TSRBH in channel 1 is shown next.

Bit	7	6	5	4	3	2	1	0
TSRBH	—	—	—	—	CMIE4	CMIE3	IMIE4	IMIE3
Initial value	1	1	1	1	0	0	0	0
R/W	—	—	—	—	R/W	R/W	R/W	R/W

Input capture/
Compare match
interrupt enable
4/3

These bits enable
and disable GR2
and GR1 compare
match and input
capture interrupts

Compare match interrupt enable 4/3

These bits enable and disable DR4
and DR3 compare match interrupts

Reserved bits

(1) Bits 7 to 4—Reserved: Read-only bits, always read as 1.

(2) Bit 3—Compare Match Interrupt Enable 4 (CMIE4): Enables or disables the DR4 compare match interrupt. For further details, see section 10.9.1, “Interrupt Timing.”

Bit 3

CMIE4	Description
0	DR4 compare match interrupt is disabled (Initial value)
1	DR4 compare match interrupt is enabled

(3) Bit 2—Compare Match Interrupt Enable 3 (CMIE3): Enables or disables the DR3 compare match interrupt. For further details, see section 10.9.1, “Interrupt Timing.”

Bit 2

CMIE3	Description
0	DR3 compare match interrupt is disabled (Initial value)
1	DR3 compare match interrupt is enabled

(4) Bit 1—Input Capture/Compare Match Interrupt Enable 4 (IMIE4): Enables or disables the GR4 compare match or input capture interrupt. For further details, see section 10.9.1, “Interrupt Timing.”

Bit 1

IMIE4	Description
0	GR4 compare match or input capture interrupt is disabled (Initial value)
1	GR4 compare match or input capture interrupt is enabled

(5) Bit 0—Input Capture/Compare Match Interrupt Enable 3 (IMIE3): Enables or disables the GR3 compare match or input capture interrupt. For further details, see section 10.9.1, “Interrupt Timing.”

Bit 0

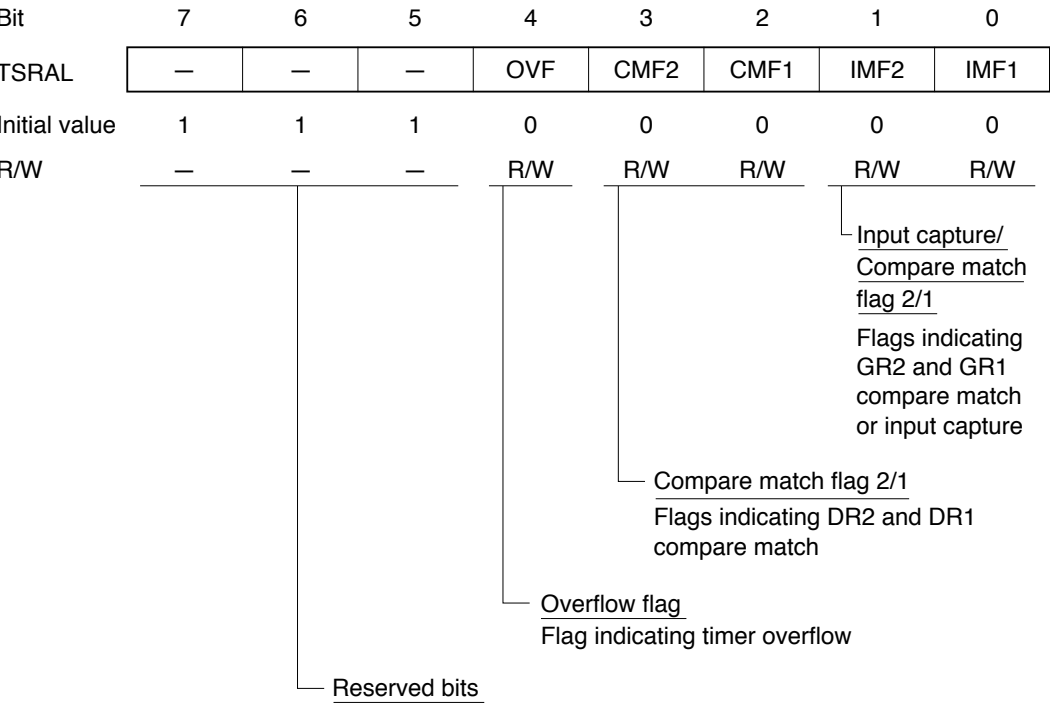

IMIE3	Description
0	GR3 compare match or input capture interrupt is disabled (Initial value)
1	GR3 compare match or input capture interrupt is enabled

10.3.5 Timer Status Register (Low)

Timer status register low (TSRL) is an eight-bit readable/writable register that indicates timer status. Writing to TSRL is restricted to clearing a flag to 0 after reading the 1 value of that flag.

After OVIE, CMIE2, CMIE1, IMIE2, or IMIE1 is set to 1 in TSRH, an interrupt is requested when OVF, CMF2, CMF1, IMF2, or IMF1 is set to 1 in TSRL.

Channel 1 has two timer status registers (low), designated TSRAL and TSRBL. Channels 2 to 7 have one TSRL each. The bit structure of TSRAL in channel 1 is shown next.

(1) **Bits 7 to 5—Reserved:** Read-only bits, always read as 1.

(2) Bit 4—Overflow Flag (OVF): Set to 1 when the counter overflows from H'FFFF to H'0000. For further details, see section 10.9.1, “Interrupt Timing.”

Bit 4

OVF	Description
0	Cleared by reading OVF after OVF is set to 1, then writing 0 in OVF (Initial value)
1	Set when counter overflow occurs

(3) Bit 3—Compare Match Flag 2 (CMF2): Set to 1 when the counter value matches the DR2 value. For further details, see section 10.9.1, “Interrupt Timing.”

Bit 3

CMF2	Description
0	1. Cleared by reading CMF2 after CMF2 is set to 1, then writing 0 in CMF2 (Initial value) 2. Cleared when the DTC is activated by a CMI2 interrupt
1	Set when DR2 compare match occurs

(4) Bit 2—Compare Match Flag 1 (CMF1): Set to 1 when the counter value matches the DR1 value. For further details, see section 10.9.1, “Interrupt Timing.”

Bit 2

CMF1	Description
0	1. Cleared by reading CMF1 after CMF1 is set to 1, then writing 0 in CMF1 (Initial value) 2. Cleared when the DTC is activated by a CMI1 interrupt
1	Set when DR1 compare match occurs

(5) Bit 1—Input Capture/Compare Match Flag 2 (IMF2): Set to 1 when the counter value matches the GR2 value, or the counter value is captured to GR2. For further details, see section 10.9.1, “Interrupt Timing.”

Bit 1

IMF2	Description
0	1. Cleared by reading IMF2 after IMF2 is set to 1, then writing 0 in IMF2 (Initial value) 2. Cleared when the DTC is activated by an IMI2 interrupt
1	Set when GR2 input capture or compare match occurs

(6) Bit 0—Input Capture/Compare Match Flag 1 (IMF1): Set to 1 when the counter value matches the GR1 value, or the counter value is captured to GR1. For further details, see section 10.9.1, “Interrupt Timing.”

Bit 0	
IMF1	Description
0	1. Cleared by reading IMF1 after IMF1 is set to 1, then writing 0 in IMF1 (Initial value) 2. Cleared when the DTC is activated by an IMI1 interrupt
1	Set when GR1 input capture or compare match occurs

TSRBL is an eight-bit readable/writable register. The bit structure of TSRBL in channel 1 is shown next.

Bit	7	6	5	4	3	2	1	0
TSRBL	—	—	—	—	CMF4	CMF3	IMF4	IMF3
Initial value	1	1	1	1	0	0	0	0
R/W	—	—	—	—	R/W	R/W	R/W	R/W

Input capture/
Compare match
flag 4/3
Flags indicating
GR2 and GR1
compare match
or input capture

Compare match flag 4/3
Flags indicating DR4 and DR3
compare match

Reserved bits

(1) Bits 7 to 4—Reserved: Read-only bits, always read as 1.

(2) Bit 3—Compare Match Flag 4 (CMF4): Set to 1 when the counter value matches the DR4 value. For further details, see section 10.9.1, “Interrupt Timing.”

Bit 3

CMF4	Description
0	1. Cleared by reading CMF4 after CMF4 is set to 1, then writing 0 in CMF4 (Initial value) 2. Cleared when the DTC is activated by a CMI4 interrupt
1	Set when DR4 compare match occurs

(3) Bit 2—Compare Match Flag 3 (CMF3): Set to 1 when the counter value matches the DR3 value. For further details, see section 10.9.1, “Interrupt Timing.”

Bit 2

CMF3	Description
0	1. Cleared by reading CMF3 after CMF3 is set to 1, then writing 0 in CMF3 (Initial value) 2. Cleared when the DTC is activated by a CMI3 interrupt
1	Set when DR3 compare match occurs

(4) Bit 1—Input Capture/Compare Match Flag 4 (IMF4): Set to 1 when the counter value matches the GR4 value, or the counter value is captured to GR4. For further details, see section 10.9.1, “Interrupt Timing.”

Bit 1

IMF4	Description
0	1. Cleared by reading IMF4 after IMF4 is set to 1, then writing 0 in IMF4 (Initial value) 2. Cleared when the DTC is activated by an IMI4 interrupt
1	Set when GR4 input capture or compare match occurs

(5) Bit 0—Input Capture/Compare Match Flag 3 (IMF3): Set to 1 when the counter value matches the GR3 value, or the counter value is captured to GR3. For further details, see section 10.9.1, “Interrupt Timing.”

Bit 0

IMF3	Description
0	1. Cleared by reading IMF3 after IMF3 is set to 1, then writing 0 in IMF3 (Initial value) 2. Cleared when the DTC is activated by an IMI3 interrupt
1	Set when GR3 input capture or compare match occurs

10.3.6 Timer Output Enable Register

The timer output enable register (TOER) is an eight-bit readable/writable register that enables or disables output of compare match signals and selects the output level.

Channel 1 has two timer output enable registers, designated TOERA and TOERB. Channels 2 to 7 have one TOER each. The bit structure of TOERA in channel 1 is shown next.

For the selection of general register (GR) functions, see section 10.3.3, “Timer Control Register (low).”

Bit	7	6	5	4	3	2	1	0
TOERA	DOE21	DOE20	DOE11	DOE10	GOE21	GOE20	GOE11	GOE10
Initial value	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
<div><div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><div></div></div></div><div><div><div></div></div><div><d (1) Bits 7 and 6—Dedicated Register Output Enable 21/20 (DOE21/20): These bits enable and disable output of the counter-DR2 compare match signal, and select the output level. For further details, see section 10.8.2, “Selection of Output Level.”

Bit 7	Bit 6	
DOE21	DOE20	Description
0	0	Compare match signal output is disabled (Initial value)
0	1	Output 0 on compare match
1	0	Output 1 on compare match
1	1	

(2) Bits 5 and 4—Dedicated Register Output Enable 11/10 (DOE11/10): These bits enable and disable output of the counter-DR1 compare match signal, and select the output level. For further details, see section 10.8.2, “Selection of Output Level.”

Bit 5	Bit 4	
DOE11	DOE10	Description
0	0	Compare match signal output is disabled (Initial value)
0	1	Output 0 on compare match
1	0	Output 1 on compare match
1	1	

(3) Bits 3 and 2—General Register Output Enable 21/20 (DOE21/20): These bits enable and disable output of the counter-GR2 compare match signal, and select the output level.

Bit 3	Bit 2	
GOE21	GOE20	Description
0	0	Compare match signal output is disabled (Initial value)
0	1	Output 0 on compare match
1	0	Output 1 on compare match
1	1	

When GR2 is used for input capture, however, compare match signal output is disabled regardless of the setting of GOE21 and GOE20. Bits 3 and 2 are thus ignored except when IEG21 = IEG20 = 0.

For further details, see section 10.8.2, “Selection of Output Level.”

(4) Bits 1 and 0—General Register Output Enable 11/10 (DOE11/10): These bits enable and disable output of the counter-GR1 compare match signal, and select the output level.

Bit 1	Bit 0		
GOE11	GOE10	Description	
0	0	Compare match signal output is disabled	(Initial value)
0	1	Output 0 on compare match	
1	0	Output 1 on compare match	
1	1		

When GR1 is used for input capture, however, compare match signal output is disabled regardless of the setting of GOE11 and GOE10. Bits 1 and 0 are thus ignored except when IEG11 = IEG10 = 0.

For further details, see section 10.8.2, “Selection of Output Level.”

TOERB is an eight-bit readable/writable register. The bit structure of TOERB in channel 1 is shown next.

For the selection of general register (GR) functions, see section 10.3.3, “Timer Control Register (low).”

Bit	7	6	5	4	3	2	1	0
TOERB	DOE41	DOE40	DOE31	DOE30	GOE41	GOE40	GOE31	GOE30
Initial value	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
<div> <div>Dedicated register output enable 41/40</div> <div>These bits enable and disable output of the counter-DR4 compare match signal, and select the output level</div> </div>			<div> <div>Dedicated register output enable 31/30</div> <div>These bits enable and disable output of the counter-DR3 compare match signal, and select the output level</div> </div>		<div> <div>General register output enable 41/40</div> <div>These bits enable and disable output of the counter-GR4 compare match signal, and select the output level</div> </div>		<div> <div>General register output enable 31/30</div> <div>These bits enable and disable output of the counter-GR3 compare match signal, and select the output level</div> </div>	

(1) Bits 7 and 6—Dedicated Register Output Enable 41/40 (DOE41/40): These bits enable and disable output of the counter-DR4 compare match signal, and select the output level. For further details, see section 10.8.2, “Selection of Output Level.”

Bit 7	Bit 6	
DOE41	DOE40	Description
0	0	Compare match signal output is disabled (Initial value)
0	1	Output 0 on compare match
1	0	Output 1 on compare match
1	1	

(2) Bits 5 and 4—Dedicated Register Output Enable 31/30 (DOE31/30): These bits enable and disable output of the counter-DR3 compare match signal, and select the output level. For further details, see section 10.8.2, “Selection of Output Level.”

Bit 5	Bit 4	
DOE31	DOE30	Description
0	0	Compare match signal output is disabled (Initial value)
0	1	Output 0 on compare match
1	0	Output 1 on compare match
1	1	

(3) Bits 3 and 2—General Register Output Enable 41/40 (GOE41/40): These bits enable and disable output of the counter-GR4 compare match signal, and select the output level.

Bit 3	Bit 2	
GOE41	GOE40	Description
0	0	Compare match signal output is disabled (Initial value)
0	1	Output 0 on compare match
1	0	Output 1 on compare match
1	1	

When GR4 is used for input capture, however, compare match signal output is disabled regardless of the setting of GOE41 and GOE40. Bits 3 and 2 are thus ignored except when IEG41 = IEG40 = 0.

For further details, see section 10.8.2, “Selection of Output Level.”

(4) Bits 1 and 0—General Register Output Enable 31/30 (GOE31/30): These bits enable and disable output of the counter-GR3 compare match signal, and select the output level.

Bit 1	Bit 0	
GOE31	GOE30	Description
0	0	Compare match signal output is disabled (Initial value)
0	1	Output 0 on compare match
1	0	Output 1 on compare match
1	1	

When GR3 is used for input capture, however, compare match signal output is disabled regardless of the setting of GOE31 and GOE30. Bits 1 and 0 are thus ignored except when IEG31 = IEG30 = 0.

For further details, see section 10.8.2, “Selection of Output Level.”

10.4 Channel 2 to 5 Registers

Channels 2 to 5 each have two general registers used for output compare and input capture, and two dedicated registers used only for output compare.

The general registers function as output compare registers after a reset. They can be switched over to input capture by setting bits IEG21 to IEG10 in the timer control registers.

Each of channels 2 to 5 can simultaneously generate a maximum of four waveforms, or can simultaneously generate two waveforms and measure two waveforms. In programmed periodic counting mode, channels 2 to 4 are used for setting the measurement period, and channel 5 is used to measure the waveform. Channels 2 and 3 can provide two-phase PWM output. See section 10.8, “Examples of Timer Operation” for details.

Figure 10-3 shows a block diagram of channels 2 to 5.

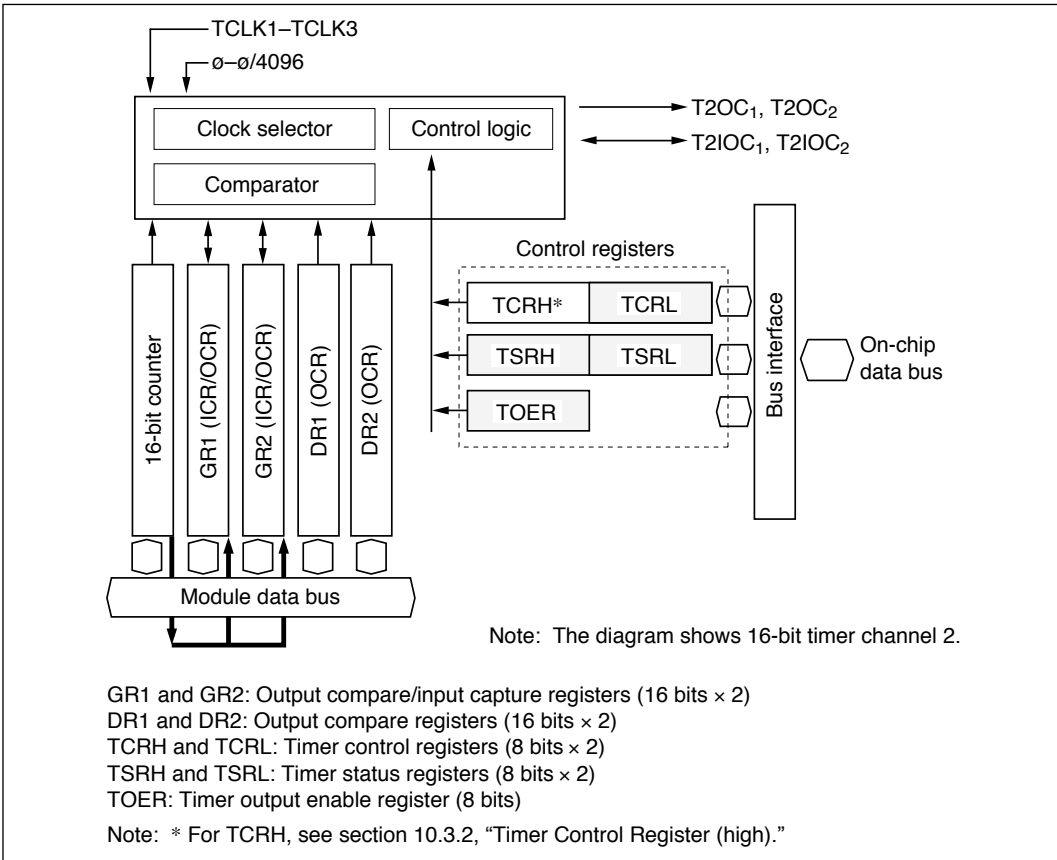

Figure 10-3 Block Diagram of Channels 2 to 5

10.4.1 Register Configuration

Table 10-3 summarizes the registers of channels 2 and 3.

Table 10-3 Registers of Channels 2 and 3

Channel	Address	Name	Abbreviation	R/W	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0	Initial Value
2	FF40	Timer control register (high)	T2CRH	R/W	—	—	CKEG1	CKEG0	TPSC3	TPSC2	TPSC1	TPSC0	H'00

10.4.2 Timer Control Register (Low)

Timer control register low (TCRL) is an eight-bit readable/writable register. For timer control register high (TCRH), see section 10.3.2, “Timer Control Register (high).” The bit structure of TCRL in channels 2 to 5 is shown next.

Bit	7	6	5	4	3	2	1	0
TCRL	—	—	CCLR1	CCLR0	IEG21	IEG20	IEG11	IEG10
Initial value	1	1	0	0	0	0	0	0
R/W	—	—	R/W	R/W	R/W	R/W	R/W	R/W

Input capture edge 21/20/11/10
These bits select register functions and the valid edges of input capture signals

Counter clear 1/0
These bits select the counter clear source

Reserved bits

(1) Bits 7 and 6 —Reserved: Read-only bits, always read as 1.

(2) Bits 5 and 4—Counter Clear 1 and 0 (CCLR1/0): These bits select the counter clear source.

Bit 5	Bit 4	
CCLR1	CCLR0	Description
0	0	Counter not cleared (Initial value)
0	1	Counter cleared on GR1 compare match or capture
1	0	Counter cleared on DR2 compare match*
1	1	Synchronous clearing of counter enabled

Note: * In channels 6 and 7 the counter is cleared on GR2 compare match or capture.

When CCLR1 = CCLR0 = 1, the counter is cleared in synchronization with the clearing of the paired timer selected in timer mode register A.

If GR1 is used as a compare register the counter is cleared by compare match. If GR1 is used as a capture register the counter is cleared by input capture.

For further details, see section 10.8.4, “Counter Clearing Function” and section 10.8.6, “Synchronizing Mode.”

(3) Bits 3 and 2—Input Capture Edge 21/20 (IEG21/20): These bits select the function of GR2 and the valid edge of the input capture signal.

Bit 3	Bit 2	Description
IEG21	IEG20	
0	0	GR2 is not used for input capture (Initial value)*
0	1	GR2 captures rising edge of input capture signal
1	0	GR2 captures falling edge of input capture signal
1	1	GR2 captures both edges of input capture signal

Note: * GR2 becomes an output compare register.

A reset clears bits IEG21 and IEG20 to 0, disabling input capture and making GR2 an output compare register. If IEG21 or IEG20 is set to 1, or both IEG21 and IEG20 are set to 1, GR2 becomes an input capture register.

For further details, see section 10.8.3, “Input Capture Function.”

(4) Bits 1 and 0—Input Capture Edge 11/10 (IEG11/10): These bits select the function of GR1 and the valid edge of the input capture signal.

Bit 1	Bit 0	Description
IEG11	IEG10	
0	0	GR1 is not used for input capture (Initial value)*
0	1	GR1 captures rising edge of input capture signal
1	0	GR1 captures falling edge of input capture signal
1	1	GR1 captures both edges of input capture signal

Note: * GR1 becomes an output compare register.

A reset clears bits IEG11 and IEG10 to 0, disabling input capture and making GR1 an output compare register. If IEG11 or IEG10 is set to 1, or both IEG11 and IEG10 are set to 1, GR1 becomes an input capture register.

For further details, see section 10.8.3, “Input Capture Function.”

10.4.3 Timer Status Register (High)

Timer status register high (TSRH) is an eight-bit readable/writable register. After OVIE, CMIE2, CMIE1, IMIE2, or IMIE1 is set to 1 in TSRH, an interrupt is requested when OVF, CMF2, CMF1, IMF2, or IMF1 is set to 1 in TSRL. The bit structure of TSRH in channels 2 to 5 is shown next.

Bit	7	6	5	4	3	2	1	0
TSRH	—	—	—	OVIE	CMIE2	CMIE1	IMIE2	IMIE1
Initial value	1	1	1	0	0	0	0	0
R/W	—	—	—	R/W	R/W	R/W	R/W	R/W

Input capture/
Compare match
interrupt enable
2/1
These bits enable
and disable GR2
and GR1 compare
match and input
capture interrupts

Compare match interrupt enable 2/1
These bits enable and disable DR2
and DR1 compare match interrupts

Overflow interrupt enable
Enables or disables timer overflow interrupts

Reserved bits

- (1) Bits 7 to 5—Reserved: Read-only bits, always read as 1.
- (2) Bit 4—Overflow Interrupt Enable (OVIE): Enables or disables the counter overflow interrupt. For further details, see section 10.9.1, “Interrupt Timing.”

Bit 4	
OVIE	Description
0	Counter overflow interrupt is disabled (Initial value)
1	Counter overflow interrupt is enabled

(3) Bit 3—Compare Match Interrupt Enable 2 (CMIE2): Enables or disables the DR2 compare match interrupt. For further details, see section 10.9.1, “Interrupt Timing.”

Bit 3

CMIE2	Description
0	DR2 compare match interrupt is disabled (Initial value)
1	DR2 compare match interrupt is enabled

(4) Bit 2—Compare Match Interrupt Enable 1 (CMIE1): Enables or disables the DR1 compare match interrupt. For further details, see section 10.9.1, “Interrupt Timing.”

Bit 2

CMIE1	Description
0	DR1 compare match interrupt is disabled (Initial value)
1	DR1 compare match interrupt is enabled

(5) Bit 1—Input Capture/Compare Match Interrupt Enable 2 (IMIE2): Enables or disables the GR2 compare match or input capture interrupt. For further details, see section 10.9.1, “Interrupt Timing.”

Bit 1

IMIE2	Description
0	GR2 input capture or compare match interrupt is disabled (Initial value)
1	GR2 input capture or compare match interrupt is enabled

(6) Bit 0—Input Capture/Compare Match Interrupt Enable 1 (IMIE1): Enables or disables the GR1 compare match or input capture interrupt. For further details, see section 10.9.1, “Interrupt Timing.”

Bit 0

IMIE1	Description
0	GR1 input capture or compare match interrupt is disabled (Initial value)
1	GR1 input capture or compare match interrupt is enabled

10.4.4 Timer Status Register (Low)

Timer status register low (TSRL) is an eight-bit readable/writable register. After OVIE, CMIE2, CMIE1, IMIE2, or IMIE1 is set to 1 in TSRH, an interrupt is requested when OVF, CMF2, CMF1, IMF2, or IMF1 is set to 1 in TSRL. Writing to TSRL is restricted to clearing a flag to 0 after reading the 1 value of that flag. The bit structure of TSRL in channels 2 to 5 is shown next.

Bit	7	6	5	4	3	2	1	0
TSRL	—	—	—	OVF	CMF2	CMF1	IMF2	IMF1
Initial value	1	1	1	0	0	0	0	0
R/W	—	—	—	R/W	R/W	R/W	R/W	R/W

Input capture/
Compare match
flag 2/1
Flags indicating
GR2 and GR1
compare match
or input capture

Compare match flag 2/1
Flags indicating DR2 and DR1
compare match

Overflow flag
Flag indicating counter overflow

Reserved bits

- (1) Bits 7 to 5—Reserved: Read-only bits, always read as 1.
- (2) Bit 4—Overflow Flag (OVF): Set to 1 when the counter overflows from H'FFFF to H'0000. For further details, see section 10.9.1, “Interrupt Timing.”

Bit 4	
OVF	Description
0	Cleared by reading OVF after OVF is set to 1, then writing 0 in OVF (Initial value)
1	Set when counter overflow occurs

(3) Bit 3—Compare Match Flag 2 (CMF2): Set to 1 when the counter value matches the DR2 value. For further details, see section 10.9.1, “Interrupt Timing.”

Bit 3

CMF2	Description
0	1. Cleared by reading CMF2 after CMF2 is set to 1, then writing 0 in CMF2 (Initial value) 2. Cleared when the DTC is activated by a CMI2 interrupt
1	Set when DR2 compare match occurs

(4) Bit 2—Compare Match Flag 1 (CMF1): Set to 1 when the counter value matches the DR1 value. For further details, see section 10.9.1, “Interrupt Timing.”

Bit 2

CMF1	Description
0	1. Cleared by reading CMF1 after CMF1 is set to 1, then writing 0 in CMF1 (Initial value) 2. Cleared when the DTC is activated by a CMI1 interrupt
1	Set when DR1 compare match occurs

(5) Bit 1—Input Capture/Compare Match Flag 2 (IMF2): Set to 1 when the counter value matches the GR2 value, or the counter value is captured to GR2. For further details, see section 10.9.1, “Interrupt Timing.”

Bit 1

IMF2	Description
0	1. Cleared by reading IMF2 after IMF2 is set to 1, then writing 0 in IMF2 (Initial value) 2. Cleared when the DTC is activated by an IMI2 interrupt
1	Set when GR2 input capture or compare match occurs

(6) Bit 0—Input Capture/Compare Match Flag 1 (IMF1): Set to 1 when the counter value matches the GR1 value, or the counter value is captured to GR1. For further details, see section 10.9.1, “Interrupt Timing.”

Bit 0

IMF1	Description
0	1. Cleared by reading IMF1 after IMF1 is set to 1, then writing 0 in IMF1 (Initial value) 2. Cleared when the DTC is activated by an IMI1 interrupt
1	Set when GR1 input capture or compare match occurs

10.4.5 Timer Output Enable Register

The timer output enable register (TOER) is an eight-bit readable/writable register. The bit structure of TOER in channels 2 to 5 is shown next.

For the selection of general register (GR) functions, see section 10.3.3, “Timer Control Register (low).”

Bit	7	6	5	4	3	2	1	0
TOER	DOE21	DOE20	DOE11	DOE10	GOE21	GOE20	GOE11	GOE10
Initial value	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
	Dedicated register output enable 21/20 These bits enable and disable output of the counter-DR2 compare match signal, and select the output level		Dedicated register output enable 11/10 These bits enable and disable output of the counter-DR1 compare match signal, and select the output level		General register output enable 21/20 These bits enable and disable output of the counter-GR2 compare match signal, and select the output level		General register output enable 11/10 These bits enable and disable output of the counter-GR1 compare match signal, and select the output level	

(1) **Bits 7 and 6—Dedicated Register Output Enable 21/20 (DOE21/20):** These bits enable and disable output of the counter-DR2 compare match signal, and select the output level. For further details, see section 10.8.2, “Selection of Output Level.”

Bit 7	Bit 6	Description
DOE21	DOE20	
0	0	Compare match signal output is disabled (Initial value)
0	1	Output 0 on compare match
1	0	Output 1 on compare match
1	1	Toggle on compare match*

Note: * Channels 2 and 3 do not have an output toggle function. If these bits are set to 11, the output goes to 1 on compare match.

(2) Bits 5 and 4—Dedicated Register Output Enable 11/10 (DOE11/10): These bits enable and disable output of the counter-DR1 compare match signal, and select the output level. For further details, see section 10.8.2, “Selection of Output Level.”

Bit 5	Bit 4	
DOE11	DOE10	Description
0	0	Compare match signal output is disabled (Initial value)
0	1	Output 0 on compare match
1	0	Output 1 on compare match
1	1	Toggle on compare match*

Note: * Channels 2 and 3 do not have an output toggle function. If these bits are set to 11, the output goes to 1 on compare match.

(3) Bits 3 and 2—General Register Output Enable 21/20 (GOE21/20): These bits enable and disable output of the counter-GR2 compare match signal, and select the output level.

Bit 3	Bit 2	
GOE21	GOE20	Description
0	0	Compare match signal output is disabled (Initial value)
0	1	Output 0 on compare match
1	0	Output 1 on compare match
1	1	Toggle on compare match*

Note: * Channels 2 and 3 do not have an output toggle function. If these bits are set to 11, the timer outputs 1 on compare match.

When GR2 is used for input capture, however, compare match signal output is disabled regardless of the setting of GOE21 and GOE20. Bits 3 and 2 are thus ignored except when IEG21 = IEG20 = 0.

For further details, see section 10.8.2, “Selection of Output Level.”

(4) Bits 1 and 0—General Register Output Enable 11/10 (GOE11/10): These bits enable and disable output of the counter-GR1 compare match signal, and select the output level.

Bit 1	Bit 0	
GOE11	GOE10	Description
0	0	Compare match signal output is disabled (Initial value)
0	1	Output 0 on compare match
1	0	Output 1 on compare match
1	1	Toggle on compare match *

Note: * Channels 2 and 3 do not have an output toggle function. If these bits are set to 11, the timer outputs 1 on compare match.

When GR1 is used for input capture, however, compare match signal output is disabled regardless of the setting of GOE11 and GOE10. Bits 1 and 0 are thus ignored except when IEG11 = IEG10 = 0.

For further details, see section 10.8.2, “Selection of Output Level.”

10.5 Channel 6 and 7 Registers

Channels 6 and 7 each have two general registers used for output compare and input capture.

The general registers function as output compare registers after a reset. They can be switched over to input capture by setting bits IEG21 to IEG10 in the timer control registers.

Each of channels 6 and 7 can simultaneously measure two waveforms and generate one waveform. Channels 6 and 7 can each be used to measure waveforms in programmed periodic counting mode. The timer counter in channel 7 can count up or down according to the phase of two external clock signals in phase counting mode. Channels 6 and 7 can provide single-phase PWM output in PWM output mode. See section 10.8, “Examples of Timer Operation” for details.

Figure 10-4 shows a block diagram of channels 6 and 7.

Figure 10-4 Block Diagram of Channels 6 and 7

10.5.1 Register Configuration

Table 10-5 summarizes the registers of channels 6 and 7.

Table 10-5 Registers of Channels 6 and 7

Chan- nel	Address	Name	Abbre- viation	R/W	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0	Initial Value

10.5.2 Timer Status Register (High)

Timer status register high (TSRH) is an eight-bit readable/writable register. After OVIE, IMIE2, or IMIE1 is set to 1 in TSRH, an interrupt is requested when OVF, IMF2, or IMF1 is set to 1 in TSRL. For timer control register high and low, see section 10.3.2, “Timer Control Register (high)” and section 10.4.2, “Timer Control Register (low).” The bit structure of TSRH in channels 6 and 7 is shown next.

Bit	7	6	5	4	3	2	1	0
TSRH	—	—	—	—	—	OVIE	IMIE2	IMIE1
Initial value	1	1	1	1	1	0	0	0
R/W	—	—	—	—	—	R/W	R/W	R/W

Reserved bits

and disable
compare match
and input capture
interrupts

Overflow interrupt enable
Enables or disables timer
overflow interrupts

- (1) Bits 7 to 3—Reserved: Read-only bits, always read as 1.
- (2) Bit 2—Overflow Interrupt Enable (OVIE): Enables or disables the counter overflow interrupt. For further details, see section 10.9.1, “Interrupt Timing.”

Bit 2	
OVIE	Description
0	Counter overflow interrupt is disabled (Initial value)
1	Counter overflow interrupt is enabled

(3) Bit 1—Input Capture/Compare Match Interrupt Enable 2 (IMIE2): Enables or disables the GR2 compare match or input capture interrupt. For further details, see section 10.9.1, “Interrupt Timing.”

Bit 1

IMIE2	Description
0	GR2 input capture or compare match interrupt is disabled (Initial value)
1	GR2 input capture or compare match interrupt is enabled

(4) Bit 0—Input Capture/Compare Match Interrupt Enable 1 (IMIE1): Enables or disables the GR1 compare match or input capture interrupt. For further details, see section 10.9.1, “Interrupt Timing.”

Bit 0

IMIE1	Description
0	GR1 input capture or compare match interrupt is disabled (Initial value)
1	GR1 input capture or compare match interrupt is enabled

10.5.3 Timer Status Register (Low)

Timer status register low (TSRL) is an eight-bit readable/writable register. After OVIE, IMIE2, or IMIE1 is set to 1 in TSRH, an interrupt is requested when OVF, IMF2, or IMF1 is set to 1 in TSRL. Writing to TSRL is restricted to clearing a flag to 0 after reading the 1 value of that flag. The bit structure of TSRL in channels 6 and 7 is shown next.

Bit	7	6	5	4	3	2	1	0
TSRL	—	—	—	—	—	OVF	IMF2	IMF1
Initial value	1	1	1	1	1	0	0	0
R/W	—	—	—	—	—	R/W	R/W	R/W

Reserved bits

Overflow flag
Flag indicating counter overflow

Input capture/
Compare match
flag 2/1
Flags indicating
GR2 and GR1
compare match
or input capture

- (1) **Bits 7 to 3—Reserved:** Read-only bits, always read as 1.
- (2) **Bit 2—Overflow Flag (OVF):** Set to 1 when the counter overflows from H'FFFF to H'0000 or when the counter in channel 7 underflows from H'0000 to H'FFFF in phase counting mode. For further details, see section 10.9.1, “Interrupt Timing.”

Bit 2	
OVF	Description
0	Cleared by reading OVF after OVF is set to 1, then writing 0 in OVF (Initial value)
1	Set when counter overflow occurs

(3) Bit 1—Input Capture/Compare Match Flag 2 (IMF2): Set to 1 when the counter value matches the GR2 value, or the counter value is captured to GR2. For further details, see section 10.9.1, “Interrupt Timing.”

Bit 1

IMF2	Description
0	1. Cleared by reading IMF2 after IMF2 is set to 1, then writing 0 in IMF2 (Initial value) 2. Cleared when the DTC is activated by an IMI2 interrupt
1	Set when GR2 input capture or compare match occurs

(4) Bit 0—Input Capture/Compare Match Flag 1 (IMF1): Set to 1 when the counter value matches the GR1 value, or the counter value is captured to GR1. For further details, see section 10.9.1, “Interrupt Timing.”

Bit 0

IMF1	Description
0	1. Cleared by reading IMF1 after IMF1 is set to 1, then writing 0 in IMF1 (Initial value) 2. Cleared when the DTC is activated by an IMI1 interrupt
1	Set when GR1 input capture or compare match occurs

10.5.4 Timer Output Enable Register

The timer output enable register (TOER) is an eight-bit readable/writable register. The bit structure of TOER in channels 6 and 7 is shown next.

For the selection of general register (GR) functions, see section 10.3.3, “Timer Control Register (low).”

Bit	7	6	5	4	3	2	1	0
TOER	—	—	—	—	GOE21	GOE20	GOE11	GOE10
Initial value	1	1	1	1	0	0	0	0
R/W	—	—	—	—	R/W	R/W	R/W	R/W

General register output enable
11/10
These bits enable and disable output of the counter-GR1 compare match signal, and select the output level

General register output enable
21/20
These bits enable and disable output of the counter-GR2 compare match signal, and select the output level

Reserved bits

(1) **Bits 7 to 4—Reserved:** Read-only bits, always read as 1.

(2) Bits 3 and 2—General Register Output Enable 21/20 (GOE21/20): These bits enable and disable output of the counter-GR2 compare match signal, and select the output level.

Bit 3	Bit 2	
GOE21	GOE20	Description
0	0	Compare match signal output is disabled (Initial value)
0	1	Output 0 on compare match
1	0	Output 1 on compare match
1	1	

When GR2 is used for input capture, however, compare match signal output is disabled regardless of the setting of GOE21 and GOE20. Bits 3 and 2 are thus ignored except when IEG21 = IEG20 = 0.

For further details, see section 10.8.2, “Selection of Output Level.”

(3) Bits 1 and 0—General Register Output Enable 11/10 (GOE11/10): These bits enable and disable output of the counter-GR1 compare match signal, and select the output level.

Bit 1	Bit 0	
GOE11	GOE10	Description
0	0	Compare match signal output is disabled (Initial value)
0	1	Output 0 on compare match
1	0	Output 1 on compare match
1	1	

When GR1 is used for input capture, however, compare match signal output is disabled regardless of the setting of GOE11 and GOE10. Bits 1 and 0 are thus ignored except when IEG11 = IEG10 = 0.

For further details, see section 10.8.2, “Selection of Output Level.”

10.6 IPU Register Descriptions

10.6.1 Timer Mode Register A

Timer mode register A (TMDRA) is an eight-bit readable/writable register that selects timer synchronizing and operating modes. The bit structure of TMDRA is shown next.

Bit	7	6	5	4	3	2	1	0
TMDRA	MD6-7	MD4-7	MD3-5	MD2-6	SYNC3	SYNC2	SYNC1	SYNC0
Initial value	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Timer synchronizing bits 3-0
These bits synchronize two timers

Timer mode 6-7, 4-7, 3-5, 2-6
These bits operate two timers in programmed periodic counting mode

(1) **Bit 7—Timer Mode 6-7 (MD6-7):** Operates channels 6 and 7 in programmed periodic counting mode.

Bit 7	
MD6-7	Description
0	Timers 6 and 7 operate normally (Initial value)
1	Timers 6 and 7 operate in programmed periodic counting mode

The counter value in channel 7 is captured to GR1 in channel 7 at intervals set in GR2 in channel 6. If channel 7 is externally clocked, the number of external events occurring in regular intervals timed by channel 6 can be counted. For further details see section 10.8.8, “Programmed Periodic Counting Mode.”

(2) Bit 6—Timer Mode 4-7 (MD4-7): Operates channels 4 and 7 in programmed periodic counting mode.

Bit 6

MD4-7	Description
0	Timers 4 and 7 operate normally (Initial value)
1	Timers 4 and 7 operate in programmed periodic counting mode

The counter value in channel 7 is captured to GR2 in channel 7 at intervals set in DR2 in channel 4. If channel 7 is externally clocked, the number of external events occurring in regular intervals timed by channel 4 can be counted. For further details see section 10.8.8, “Programmed Periodic Counting Mode.”

(3) Bit 5—Timer Mode 3-5 (MD3-5): Operates channels 3 and 5 in programmed periodic counting mode.

Bit 5

MD3-5	Description
0	Timers 3 and 5 operate normally (Initial value)
1	Timers 3 and 5 operate in programmed periodic counting mode

The counter value in channel 5 is captured to GR1 in channel 5 at intervals set in DR2 in channel 3. If channel 5 is externally clocked, the number of external events occurring in regular intervals timed by channel 3 can be counted. For further details see section 10.8.8, “Programmed Periodic Counting Mode.”

(4) Bit 4—Timer Mode 2-6 (MD2-6): Operates channels 2 and 6 in programmed periodic counting mode.

Bit 4

MD2-6	Description
0	Timers 2 and 6 operate normally (Initial value)
1	Timers 2 and 6 operate in programmed periodic counting mode

The counter value in channel 6 is captured to GR1 in channel 6 at intervals set in DR2 in channel 2. If channel 6 is externally clocked, the number of external events occurring in regular intervals timed by channel 2 can be counted. For further details see section 10.8.8, “Programmed Periodic Counting Mode.”

(5) Bit 3—Timer Synchronizing Bit 3 (SYNC3): Synchronizes two timer channels.

Bit 3		
SYNC3	Description	
0	Timer counters in channels 6 and 7 operate independently	(Initial value)
1	Timer counters in channels 6 and 7 are synchronized	

When SYNC3 = 1, timer counters can be preset and cleared in synchronization. If two or more bits among SYNC3, SYNC2, SYNC1, and SYNC0 are set to 1 simultaneously, all selected timer counters are synchronized. For further details, see section 10.8.6 “Synchronizing Mode.”

(6) Bit 2—Timer Synchronizing Bit 2 (SYNC2): Synchronizes two timer channels.

Bit 2		
SYNC2	Description	
0	Timer counters in channels 4 and 5 operate independently	(Initial value)
1	Timer counters in channels 4 and 5 are synchronized	

When SYNC2 = 1, timer counters can be preset and cleared in synchronization. If two or more bits among SYNC3, SYNC2, SYNC1, and SYNC0 are set to 1 simultaneously, all selected timer counters are synchronized. For further details, see section 10.8.6 “Synchronizing Mode.”

(7) Bit 1—Timer Synchronizing Bit 1 (SYNC1): Synchronizes two timer channels.

Bit 1		
SYNC1	Description	
0	Timer counters in channels 2 and 3 operate independently	(Initial value)
1	Timer counters in channels 2 and 3 are synchronized	

When SYNC1 = 1, timer counters can be preset and cleared in synchronization. If two or more bits among SYNC3, SYNC2, SYNC1, and SYNC0 are set to 1 simultaneously, all selected timer counters are synchronized. For further details, see section 10.8.6 “Synchronizing Mode.”

(8) Bit 0—Timer Synchronizing Bit 0 (SYNC0): Synchronizes two timer channels.

Bit 0		
SYNC0	Description	
0	Timer counters in channel 1 and other channels operate independently	(Initial value)
1	Timer counters in channel 1 and other channels are synchronized	

When SYNC0 = 1, timer counters can be preset and cleared in synchronization. If two or more bits among SYNC3, SYNC2, SYNC1, and SYNC0 are set to 1 simultaneously, all selected timer counters are synchronized. For further details, see section 10.8.6 “Synchronizing Mode.”

10.6.2 Timer Mode Register B

Timer mode register B (TMDRB) is an eight-bit readable/writable register that selects timer operating modes. The bit structure of TMDRB is shown next.

Bit	7	6	5	4	3	2	1	0
TMDRB	—	—	MDF	PWM4	PWM3	PWM2	PWM1	PWM0
Initial value	1	1	0	0	0	0	0	0
R/W	—	—	R/W	R/W	R/W	R/W	R/W	R/W

Reserved bits

Phase counting mode
Operates channel 7 in phase counting mode

PWM timer mode 4-0
These bits operate channels 7, 6, 3, 2, and 1 as pulse-width modulators

- (1) **Bits 7 and 6—Reserved:** Read-only bits, always read as 1.
- (2) **Bit 5—Phase Counting Mode (MDF):** Operates channel 7 in phase counting mode. For further details see section 10.8.9, “Phase Counting Mode.”

Bit 5

MDF	Description
0	Channel 7 operates normally (Initial value)
1	Channel 7 operates in phase counting mode

(3) **Bit 4—PWM Timer Mode 4 (PWM4):** Operates channel 7 as a pulse-width modulator.

Bit 4	
PWM4	Description
0	Channel 7 operates normally (Initial value)
1	Channel 7 operates as a pulse-width modulator

Channel 7 operates as a pulse-width modulator with independent period and duty cycle, providing one PWM output. When PWM4 = 1, settings of GOE11 and GOE10 in the channel 7 timer output enable register (TOER) are ignored. For further details, see section 10.8.5 “PWM Output Mode.”

(4) **Bit 3—PWM Timer Mode 3 (PWM3):** Operates channel 6 as a pulse-width modulator.

Bit 3	
PWM3	Description
0	Channel 6 operates normally (Initial value)
1	Channel 6 operates as a pulse-width modulator

Channel 6 operates as a pulse-width modulator with independent period and duty cycle, providing one PWM output. When PWM3 = 1, settings of GOE11 and GOE10 in the channel 6 timer output enable register (TOER) are ignored. For further details, see section 10.8.5 “PWM Output Mode.”

(5) **Bit 2—PWM Timer Mode 2 (PWM2):** Operates channel 3 as a pulse-width modulator.

Bit 2	
PWM2	Description
0	Channel 3 operates normally (Initial value)
1	Channel 3 operates as a pulse-width modulator

Channel 3 operates as a pulse-width modulator with independent period and duty cycle. Channel 3 can provide two-phase PWM output. When PWM2 = 1, settings of GOE21, GOE20, GOE11, and GOE10 in the channel 3 timer output enable register (TOER) are ignored. For further details, see section 10.8.5 “PWM Output Mode.”

(6) Bit 1—PWM Timer Mode 1 (PWM1): Operates channel 2 as a pulse-width modulator.

Bit 1

PWM1	Description
0	Channel 2 operates normally (Initial value)
1	Channel 2 operates as a pulse-width modulator

Channel 2 operates as a pulse-width modulator with independent period and duty cycle. Channel 2 can provide two-phase PWM output. When PWM1 = 1, settings of GOE21, GOE20, GOE11, and GOE10 in the channel 2 timer output enable register (TOER) are ignored. For further details, see section 10.8.5 “PWM Output Mode.”

(7) Bit 0—PWM Timer Mode 0 (PWM0): Operates channel 1 as a pulse-width modulator.

Bit 0

PWM0	Description
0	Channel 1 operates normally (Initial value)
1	Channel 1 operates as a pulse-width modulator

Channel 1 operates as a pulse width modulator with independent period and duty cycle. Channel 1 can provide three-phase PWM output. When PWM0 = 1, settings of DOE11, DOE10, GOE21, GOE20, GOE11, and GOE10 in the channel 1 timer output enable register (TOER) are ignored. For further details, see section 10.8.5 “PWM Output Mode.”

10.6.3 Timer Start Register

The timer start register (TSTR) is an eight-bit readable/writable register that starts and stops the counters. The bit structure of TSTR is shown next.

Bit	7	6	5	4	3	2	1	0
TSTR	—	STR7	STR6	STR5	STR4	STR3	STR2	STR1
Initial value	1	0	0	0	0	0	0	0
R/W	—	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Reserved bit

Counter start 7 to 1
These bits start and stop the counters

- (1) **Bit 7—Reserved:** Read-only bit, always read as 1.
- (2) **Bit 6—Counter Start 7 (STR7):** Starts and stops the counter in channel 7.

Bit 6	
STR7	Description
0	Timer counter 7 is halted (Initial value)
1	Timer counter 7 is counting

- (3) **Bit 5—Counter Start 6 (STR6):** Starts and stops the counter in channel 6.

Bit 5	
STR6	Description
0	Timer counter 6 is halted (Initial value)
1	Timer counter 6 is counting

- (4) **Bit 4—Counter Start 5 (STR5):** Starts and stops the counter in channel 5.

Bit 4	
STR5	Description
0	Timer counter 5 is halted (Initial value)
1	Timer counter 5 is counting

(5) **Bit 3—Counter Start 4 (STR4):** Starts and stops the counter in channel 4.

Bit 3

STR4	Description	
0	Timer counter 4 is halted	(Initial value)
1	Timer counter 4 is counting	

(6) **Bit 2—Counter Start 3 (STR3):** Starts and stops the counter in channel 3.

Bit 2

STR3	Description	
0	Timer counter 3 is halted	(Initial value)
1	Timer counter 3 is counting	

(7) **Bit 1—Counter Start 2 (STR2):** Starts and stops the counter in channel 2.

Bit 1

STR2	Description	
0	Timer counter 2 is halted	(Initial value)
1	Timer counter 2 is counting	

(8) **Bit 0—Counter Start 1 (STR1):** Starts and stops the counter in channel 1.

Bit 0

STR1	Description	
0	Timer counter 1 is halted	(Initial value)
1	Timer counter 1 is counting	

10.7 H8/500 CPU Interface

Some IPU registers can be accessed 16 bits at a time, while others are limited to eight-bit access. These two types of registers differ in their write timing, as explained next.

10.7.1 16-Bit Accessible Registers

The timer counters (TCNT), general registers (GR), and dedicated registers (DR) are 16-bit registers. The H8/500 CPU can access these registers a word at a time using a 16-bit data bus. Byte access is also possible.

Figure 10-5 shows an example of word write timing to a timer counter. Figure 10-6 shows an example of byte write timing to a timer counter.

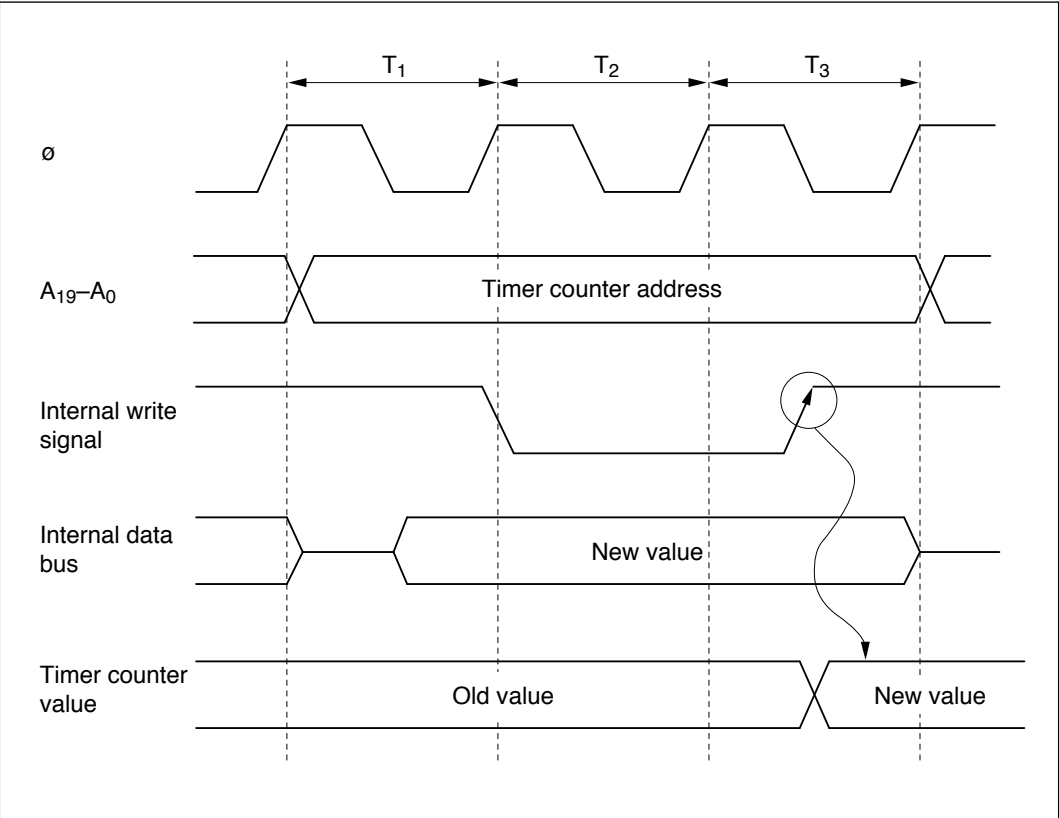

Figure 10-5 Example of Word Write Timing for Timer Counter

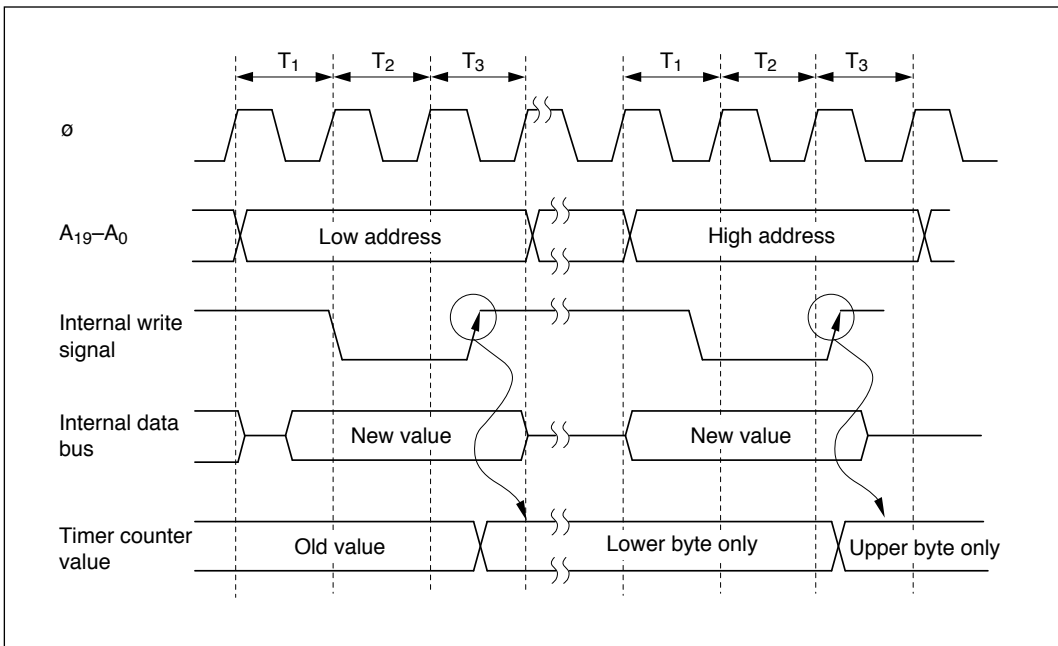

Figure 10-6 Example of Byte Write Timing for Timer Counter

- Read and Write Operations:** Timer counters, general registers, and dedicated registers can be written and read a word at a time or a byte at a time. Figure 10-7 illustrates word read/write operations. Figure 10-8 illustrates upper byte read/write operations. Figure 10-9 illustrates lower byte read/write operations.

Figure 10-7 Word Read/Write Operations

Figure 10-8 Upper Byte Read/Write Operations

Figure 10-9 Lower Byte Read/Write Operations

10.7.2 Eight-Bit Accessible Registers

The IPU’s timer control registers (TCRH, TCRL, and TCRA), timer status registers (TSRH and TSRL), timer output enable registers (TOER), timer mode register A (TMDA), timer mode register B (TMDB), and timer start register (TSTR) are eight-bit registers. The H8/500 CPU accesses these registers a byte at a time using an eight-bit data bus. If an instruction specifies word size, two registers are accessed at consecutive addresses, upper byte (even address) first and lower byte (odd address) second.

Figure 10-10 shows an example of byte write timing to a timer control register. Figure 10-11 shows an example of write timing to a timer control register by an instruction specifying word operand size.

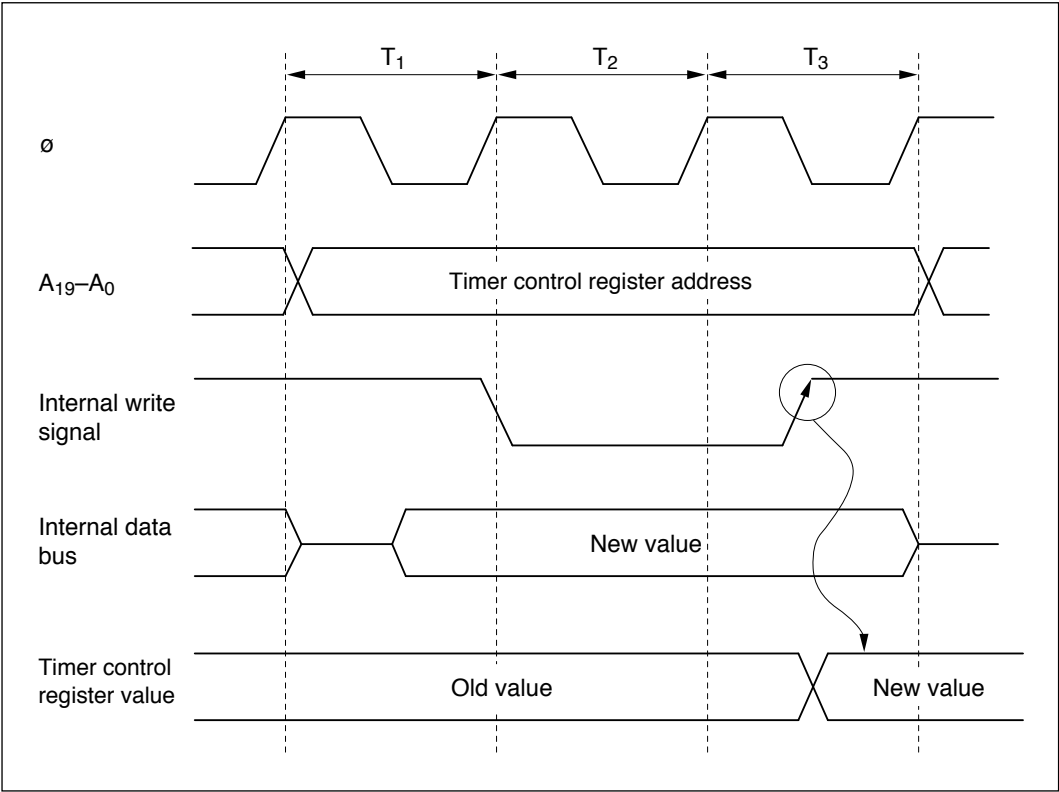

Figure 10-10 Example of Byte Write Timing for Timer Control Register

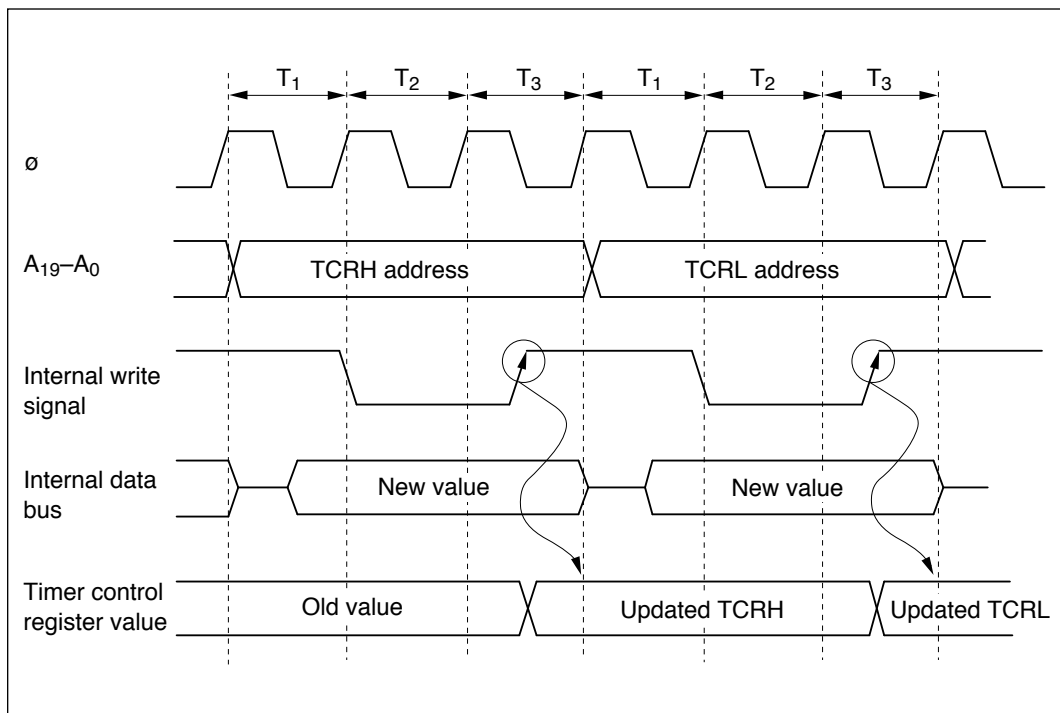

Figure 10-11 Example of Write Timing for Timer Control Register by Instruction Specifying Word Operand Size

- **Read and Write Operations:** Table 10-6 lists the byte-accessed registers. Figure 10-12 illustrates upper byte read/write operations. Figure 10-13 illustrates lower byte read/write operations.

Table 10-6 Eight-Bit Access Registers

Name	Abbreviation		
	Byte Access	Word Access	
Timer control registers (high)	TCRH	TCR	Upper
Timer control registers (low)	TCRL		Lower
Timer status registers (high)	TSRH	TSR	Upper
Timer status registers (low)	TSRL		Lower
Timer output enable registers	TOER	TOER	Upper
Timer mode registers	TMDR	TMDR	Lower
Timer start register	TSTR	TSTR	Upper
		T1CRB	Lower

Figure 10-12 Upper Byte Read/Write Operations

Figure 10-13 Lower Byte Read/Write Operations

10.8 Examples of Timer Operation

The 16-bit integrated-timer pulse unit (IPU) has several application-oriented operating modes. These are outlined and examples are given below.

10.8.1 Examples of Counting

When a start (STR) bit in the timer start register (TSTR) is set to 1, the corresponding counter starts counting from H'0000. There are two counting modes: a free-running mode and a periodic mode. Figure 10-14 shows the procedure for selecting the counting mode.

Procedure for Selecting Counting Mode

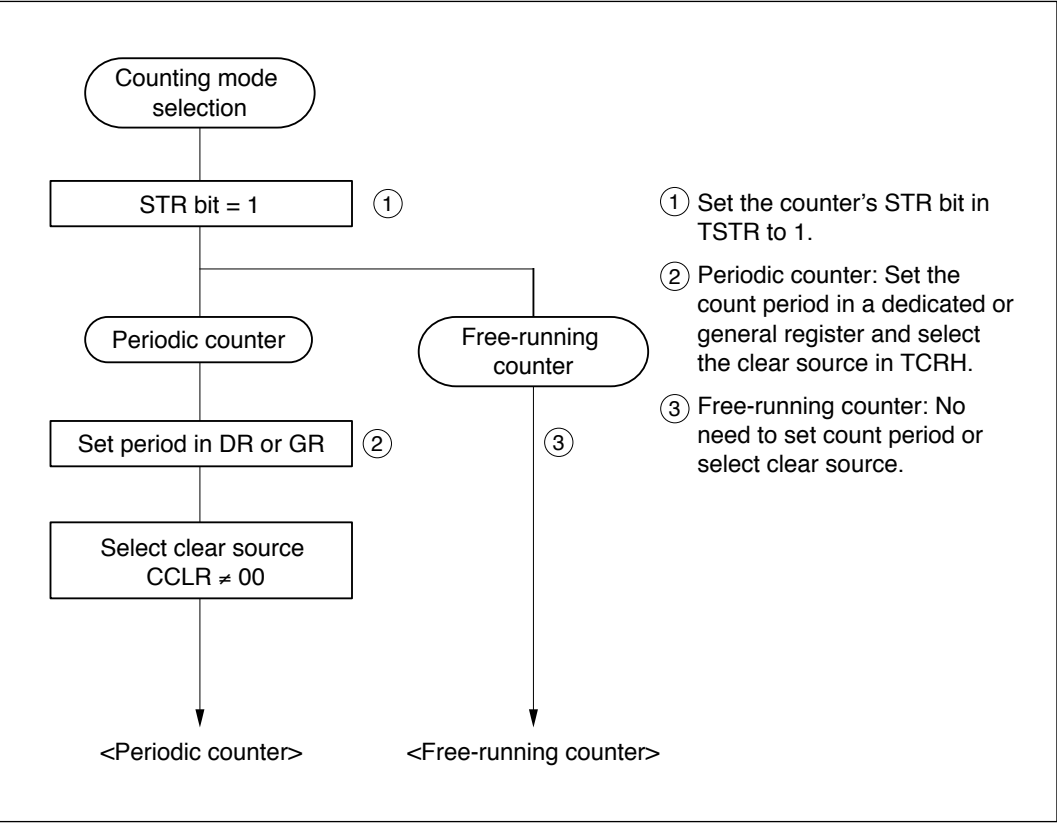

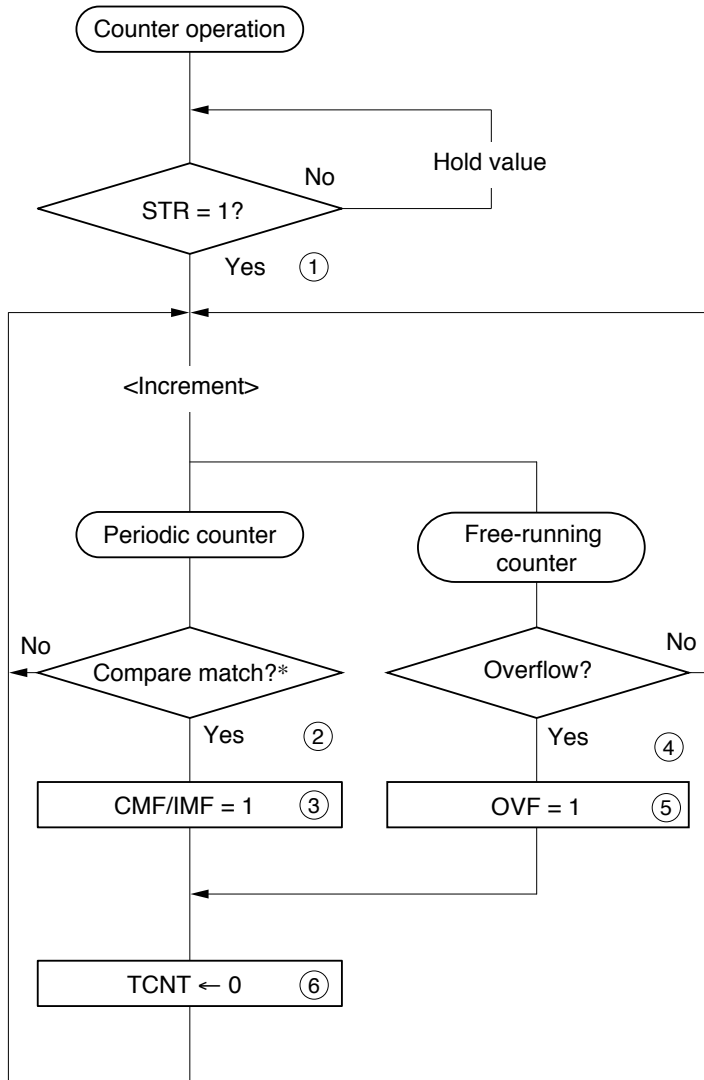

Figure 10-14 Procedure for Selecting Counting Mode

Counter Operation: Figure 10-15 illustrates counter operations.

- ① When an STR bit is set to 1, the corresponding counter starts counting up.
- ② Periodic counter: After incrementing, the counter value is checked against the count period.
- ③ Periodic counter: If the counter value matches the count period, the CMF or IMF bit in TSRL is set to 1.
- ④ Free-running counter: After incrementing, counter overflow is checked.
- ⑤ Free-running counter: If the count has overflowed, the OVF bit in TSRL is set to 1.
- ⑥ The timer counter is reset and starts counting up again from zero.

Note: * TCNT = count period

Figure 10-15 Counter Operation

A reset leaves the IPU in free-running mode. Figure 10-16 shows an example of free-running counting. The counter starts from H'0000, counts up to H'FFFF, then returns to H'0000, at which point the OVF flag is set in timer status register high (TSRH). Counting then continues from H'0000.

If compare match is selected as a counter clear source, the IPU operates in periodic counting mode. Figure 10-17 shows an example of periodic counting. The counter starts from H'0000 and counts up to H'8000. At this point a compare match with DR2 occurs, so the CMF2 flag in TSRH is set to 1 and the counter is automatically cleared. Counting then continues from H'0000.

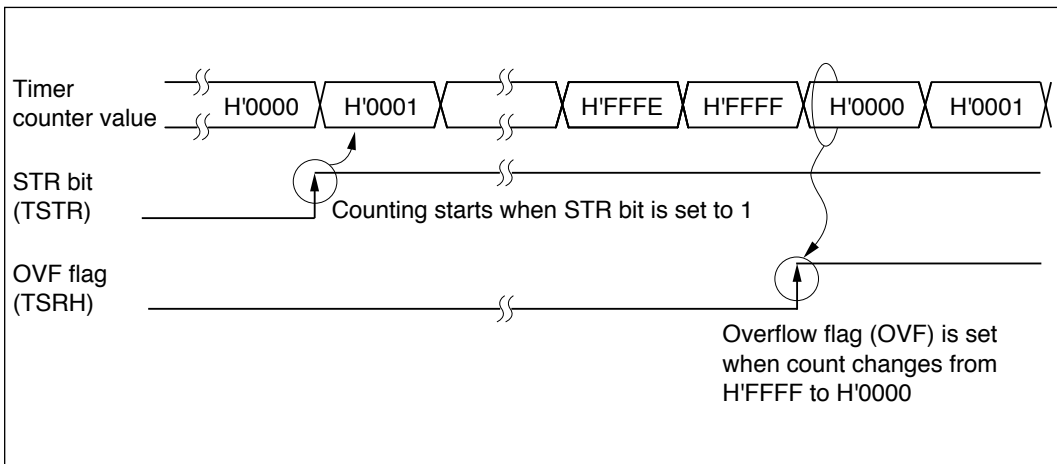

Figure 10-16 Free-Running Counter Operation

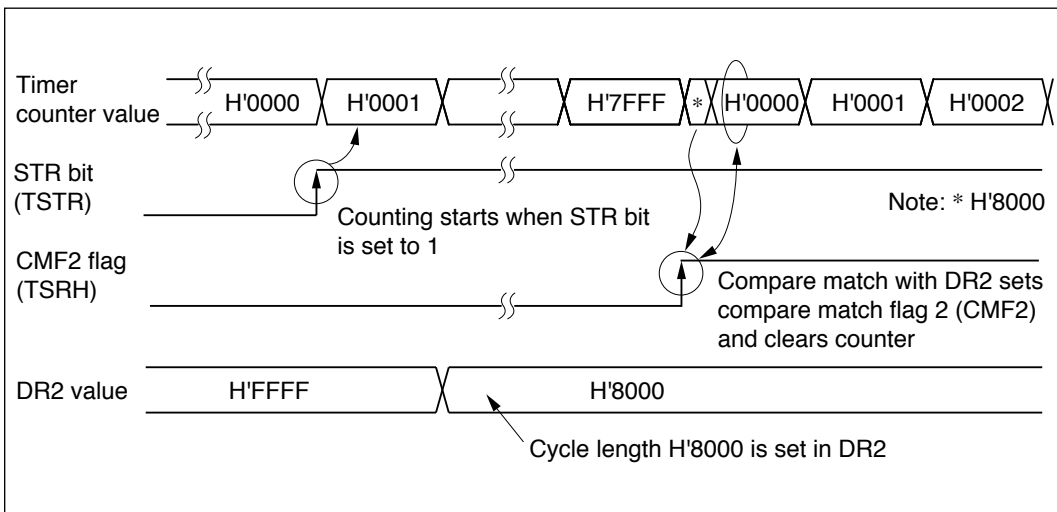

Figure 10-17 Periodic Counter Operation

10.8.2 Selection of Output Level

Compare match signals can be output in three modes: high, low, or toggle. Figure 10-18 shows the procedure for selecting the output level.

Procedure for Selecting Output Level

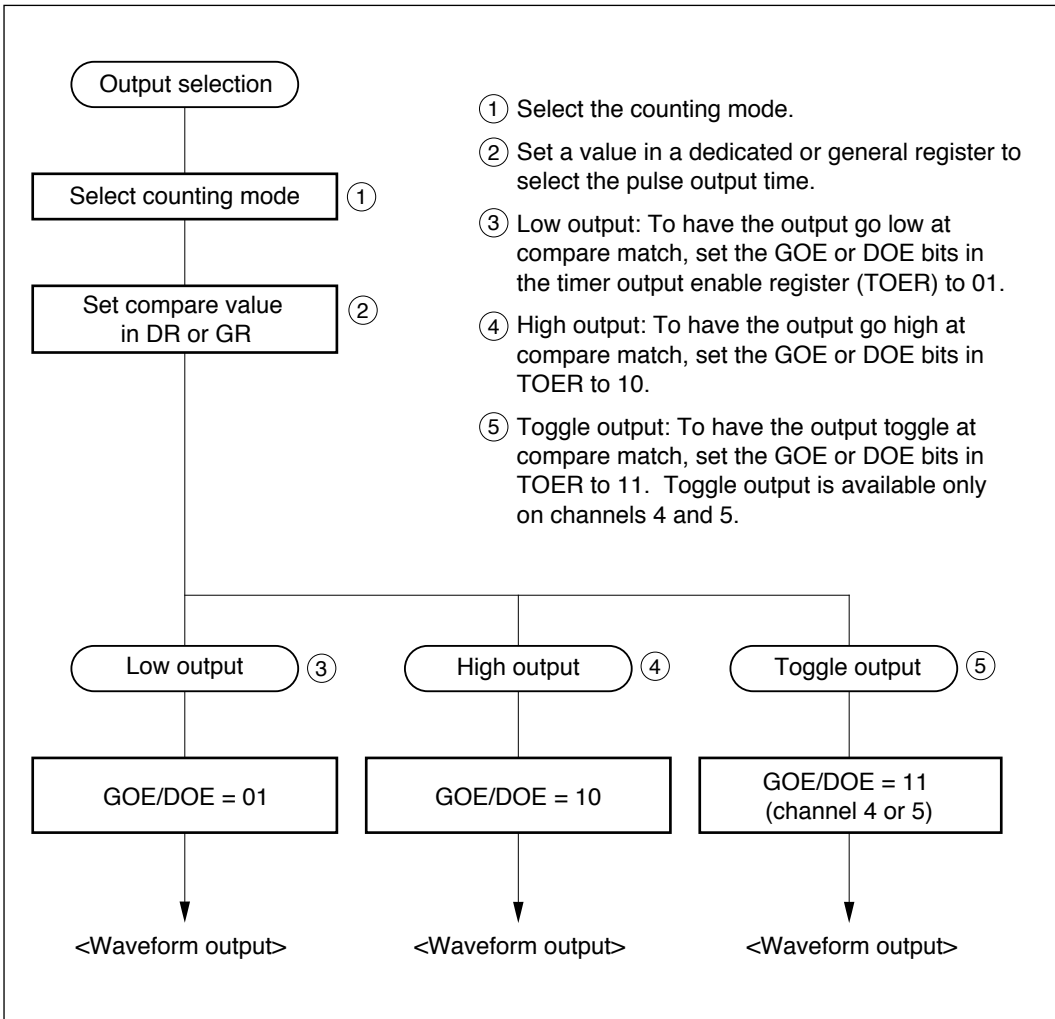

Figure 10-18 Procedure for Selecting Output Level

Waveform Output Operation: Figure 10-19 illustrates waveform output operations.

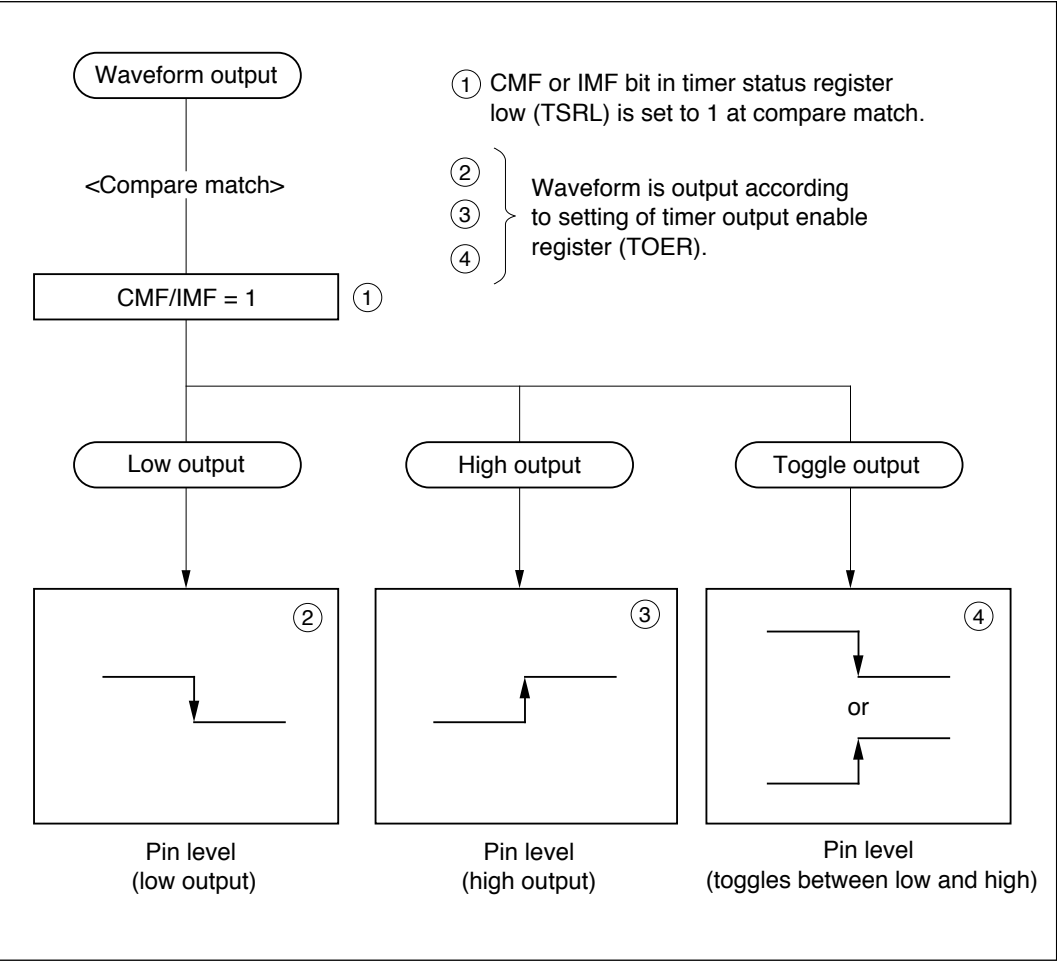

Figure 10-19 Waveform Output

Figure 10-20 shows examples of waveform output on channel 4. High output is selected from T4IOC₁, low output from T4IOC₂, and toggle output from T4OC₁.

High output is selected by setting bits GOE11 and GOE10 to 10 in the channel 4 timer output enable register (TOER). The IPU drives T4IOC₁ high when the counter matches the value in GR1 (H'0001). Low output is selected by setting bits GOE21 and GOE20 to 01 in the channel 4 TOER. The IPU drives T4IOC₂ low when the counter matches the value in GR2 (H'0003). Toggle output is selected by setting bits DOE11 and DOE10 to 11 in the channel 4 TOER. The IPU toggles T4OC₁ when the counter matches the value in DR1 (H'0004). The counter is cleared when the count matches the value in DR2 (H'00FF).

If high or low output is selected, when compare match occurs, and if the pin is already at the selected output level, the output level does not change.

- Settings

- TOER (channel 4): H'36
- TCRL (channel 4): H'E0 (clear on T4DR2 compare match)

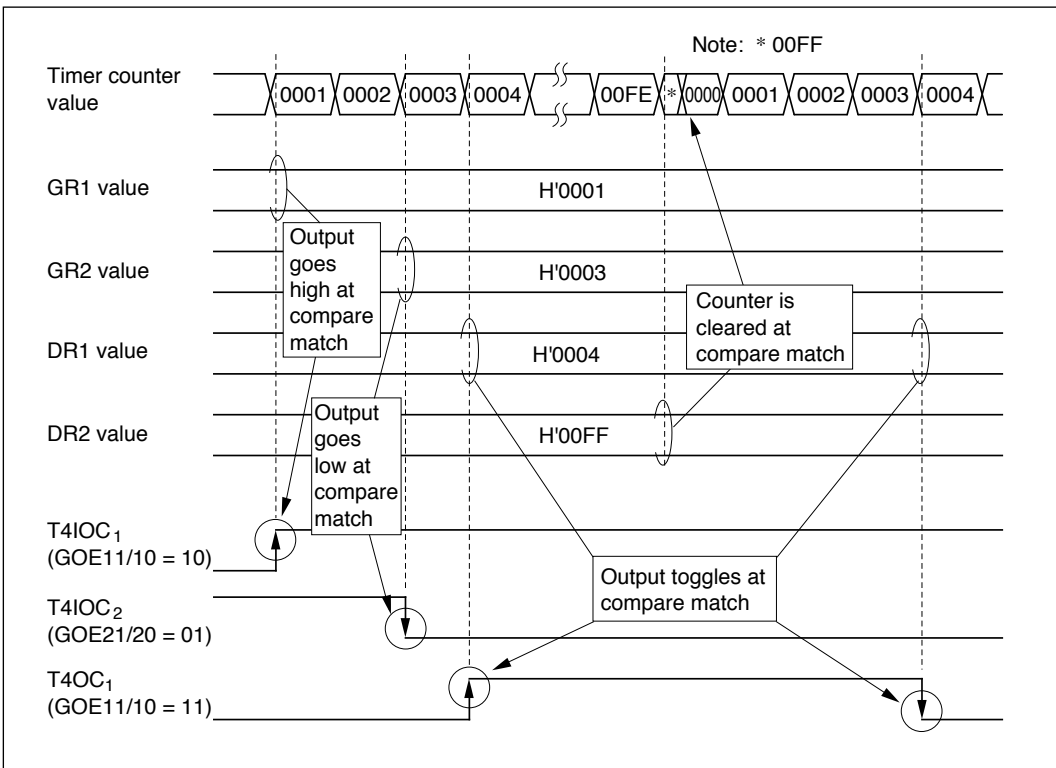

Figure 10-20 Example of Waveform Output on Channel 4

10.8.3 Input Capture Function

The counter value can be captured into a register when a transition occurs at an input capture pin. Capture can take place on the rising edge, falling edge, or both edges. Figure 10-21 shows the procedure for selecting the input capture function.

Procedure for Selecting Input Capture Mode

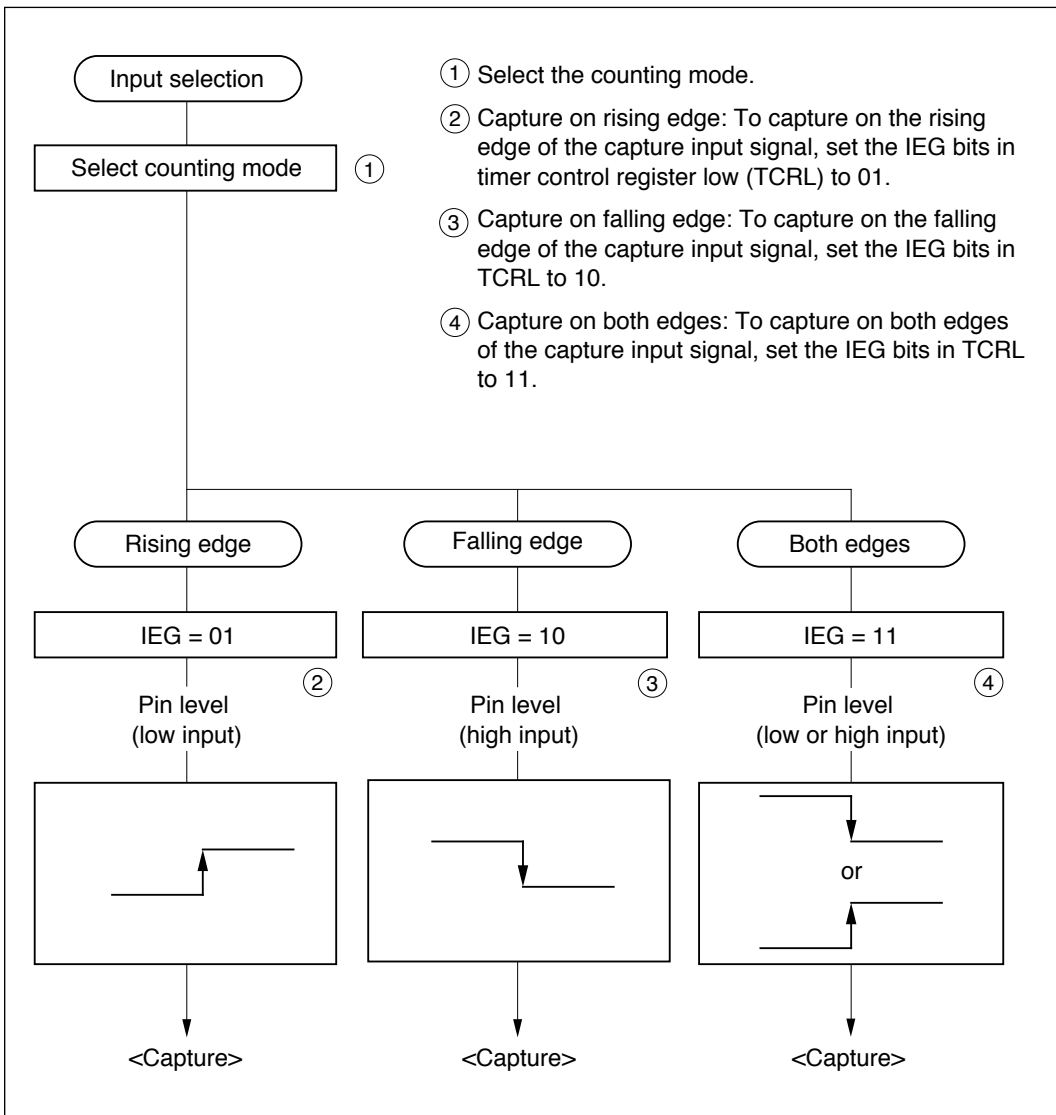

Figure 10-21 Procedure for Selecting Capture Input Mode

Capture Operation: Figure 10-22 illustrates input capture operations.

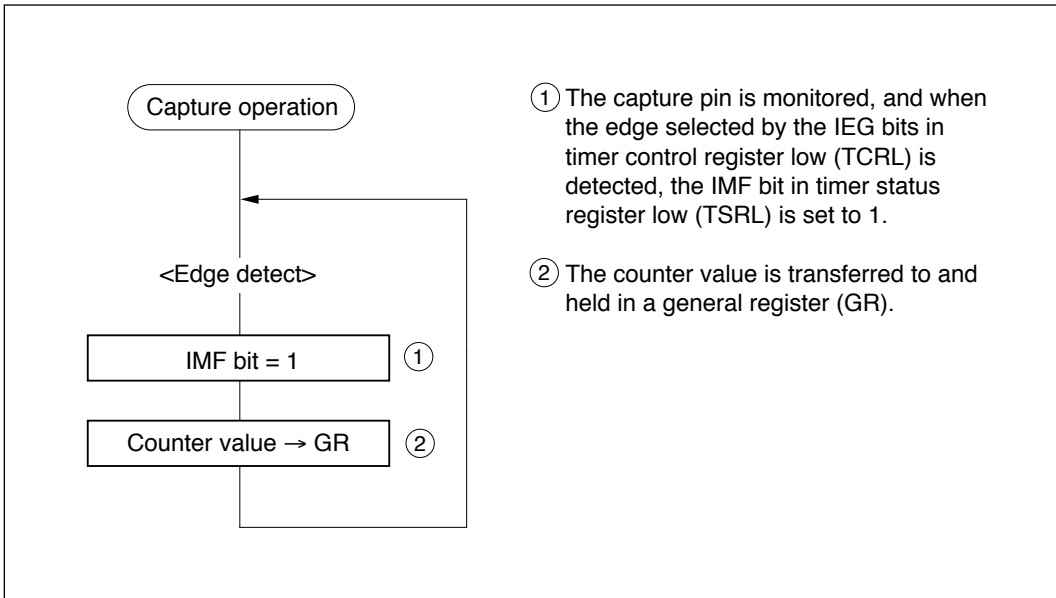

Figure 10-22 Capture Mode Operation

Figure 10-23 shows an example of pulse input capture at T1IOC₁, T1IOC₂, and T1IOC₃ on channel 1.

The rising edge of T1IOC₁ is selected by setting bits IEG11 and IEG10 to 01 in channel 1 timer control register low (TCRL). The IPU transfers the counter value (H'0001 and H'0100) to GR1 on the rising edge of the T1IOC₁ input. The falling edge of T1IOC₂ is selected by setting bits IEG21 and IEG20 in channel 1 TCRL to 10. The IPU transfers the counter value (H'0002 and H'0102) to GR2 on the falling edge of the T1IOC₂ input. The rising and falling edges of T1IOC₃ are selected by setting bits IEG31 and IEG30 in channel 1 timer control register A (TCRA) to 11. The IPU transfers the counter value (H'0004) on the rising edge and the value (H'0104) on the falling edge of the T1IOC₃ input to GR3.

- Settings
 - TCRL: H'89
 - TCRA: H'F3

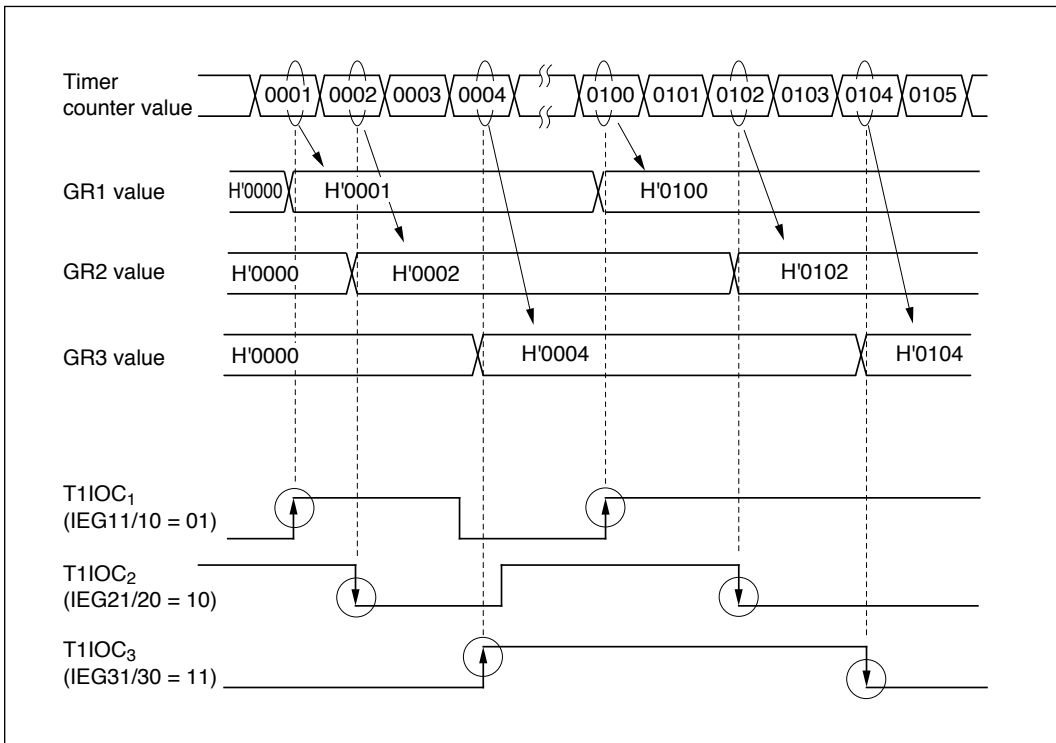

Figure 10-23 Example of Input Capture on Channel 1

Figure 10-24 shows an example of input capture timing on channel 2. The IPU latches the input capture signal input at the T2IOC₁ pin on the rising edge of the system clock (ϕ). One system clock cycle ($1.0t_{CYC}$) after the input capture signal is latched, the counter value ($n + 1$) is transferred to T2GR1. The IMF1 flag in timer status register low (TSRL) is set $1.5t_{CYC}$ after the input capture signal is latched.

The pulse width of the input capture signal must be at least $1.5t_{CYC}$.

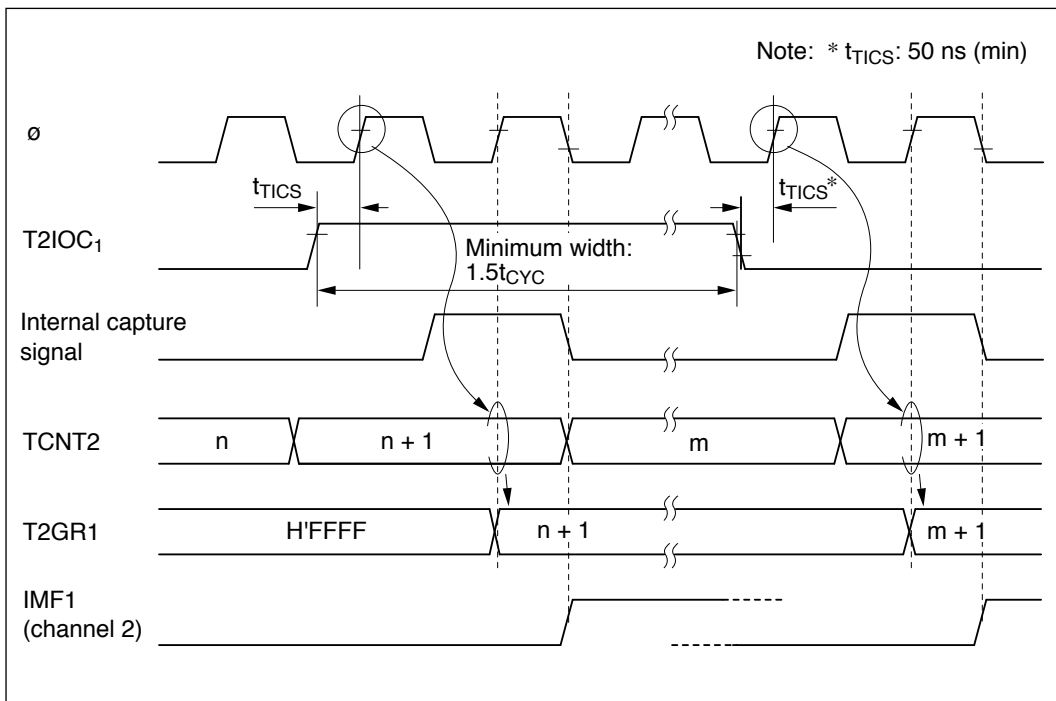

Figure 10-24 Capture Input Timing

10.8.4 Counter Clearing Function

A counter can be cleared by input capture or compare match. When compare match is selected as a counter clear source, the count repeats cyclically from H'0000 to the value in the compare register. When input capture is selected as a counter clear source, the counter can be cleared at intervals determined by external events. Figure 10-25 shows the procedure for selecting the counter clear source.

Procedure for Selecting Counter Source

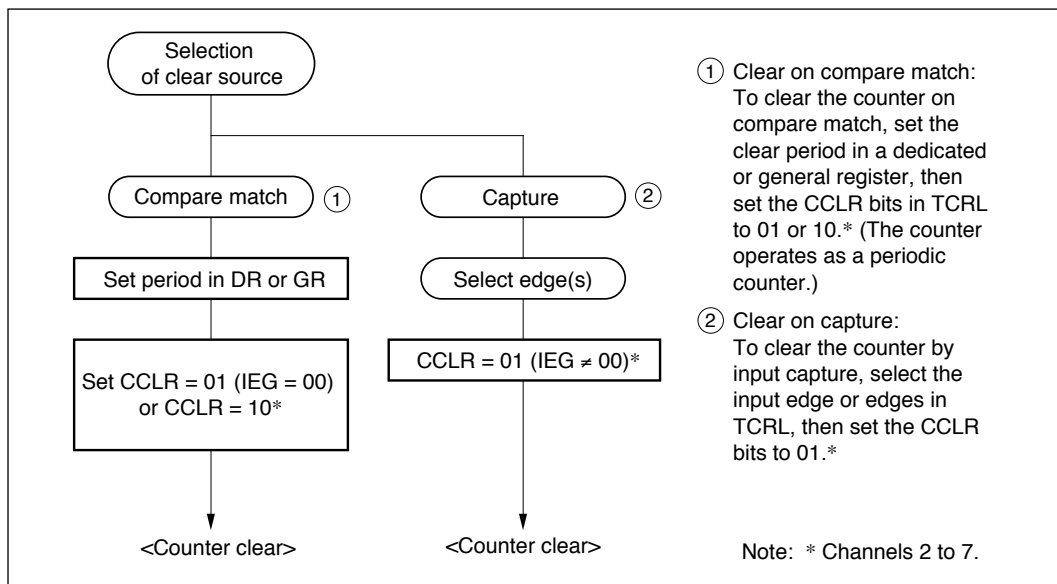

Figure 10-25 Procedure for Selecting Counter Clear Source

Counter Clear Operation: Figure 10-26 illustrates the counter clear operation.

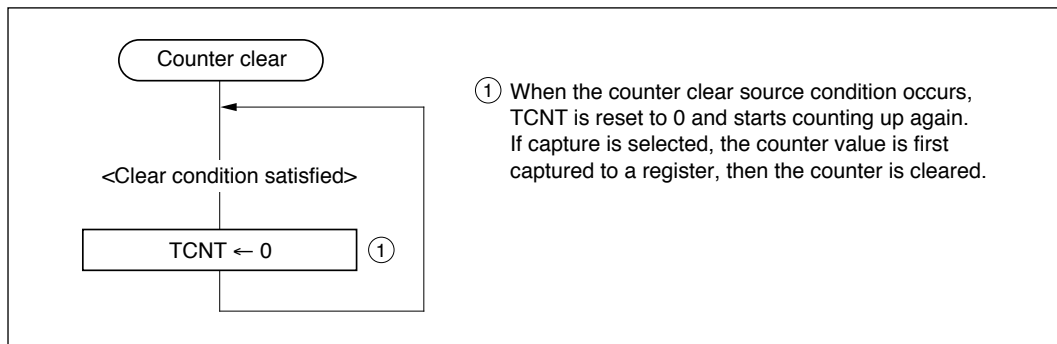

Figure 10-26 Counter Clearing Operation

Figure 10-27 shows an example of counter clearing on channel 4.

In this example the channel-4 counter is cleared by input capture at $T4IOC_1$. This clear condition is selected by setting CCLR1 and CCLR0 in channel 4 timer control register low (TCRL) to 01. The rising edge is selected by setting IEG11 and IEG10 to 01. The IPU transfers the counter value (H'0003) on the rising edge of the $T4IOC_1$ input to GR1, then clears the counter.

To clear the counter on DR2 compare match, set CCLR1 and CCLR0 to 10 in TCRL.

- Settings
 - TCRL (channel 4): H'D4 (to clear on input capture to T4GR1)
 - TCRL (channel 4): H'E0 (to clear on compare match with T4DR2)

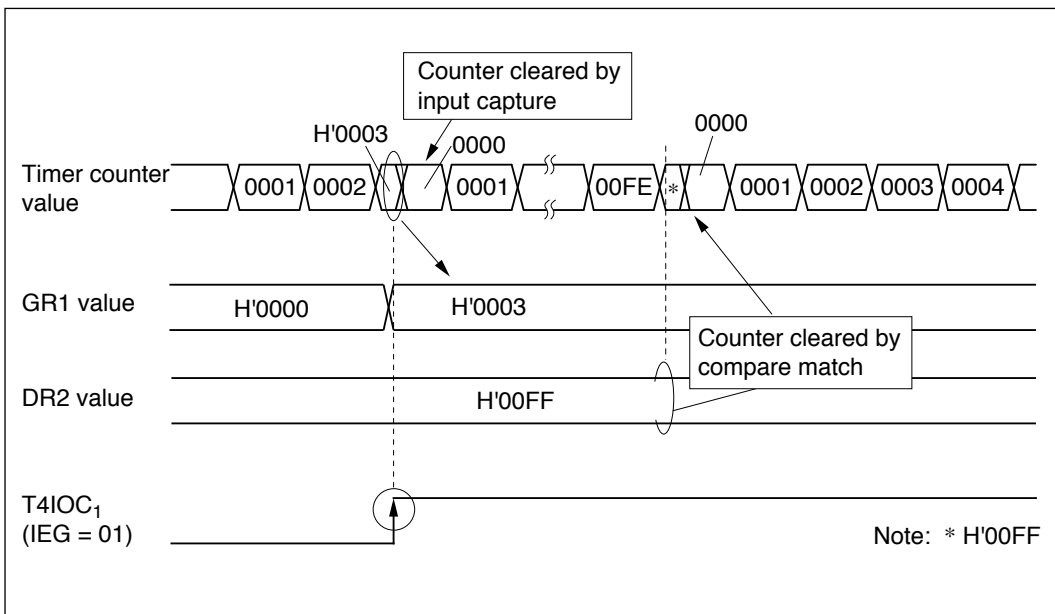

Figure 10-27 Example of Input Counter Clearing on Channel 4

10.8.5 PWM Output Mode

Channels 1, 2, 3, 6, and 7 can be used as pulse-width modulators. Channel 1 can provide three-phase PWM output, channels 2 and 3 can provide two-phase PWM output, and channels 6 and 7 can provide single-phase PWM output. Figure 10-28 shows the procedure for selecting PWM output mode.

Procedure for Selecting PWM Mode

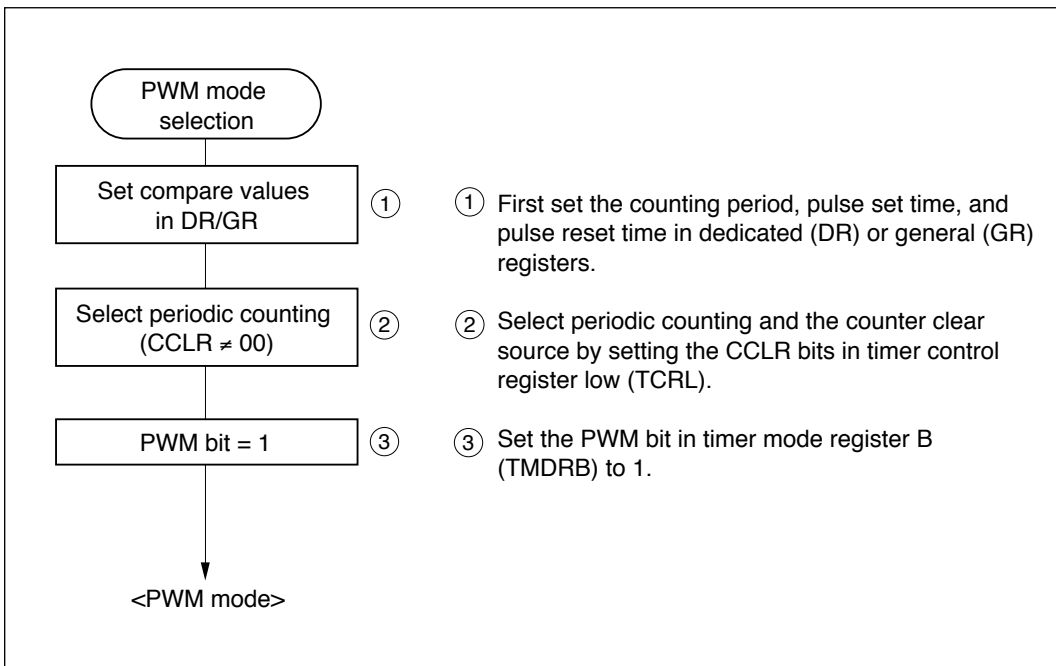

Figure 10-28 Procedure for Selecting PWM Output Mode

PWM Output Operation: Figure 10-29 illustrates PWM output operations.

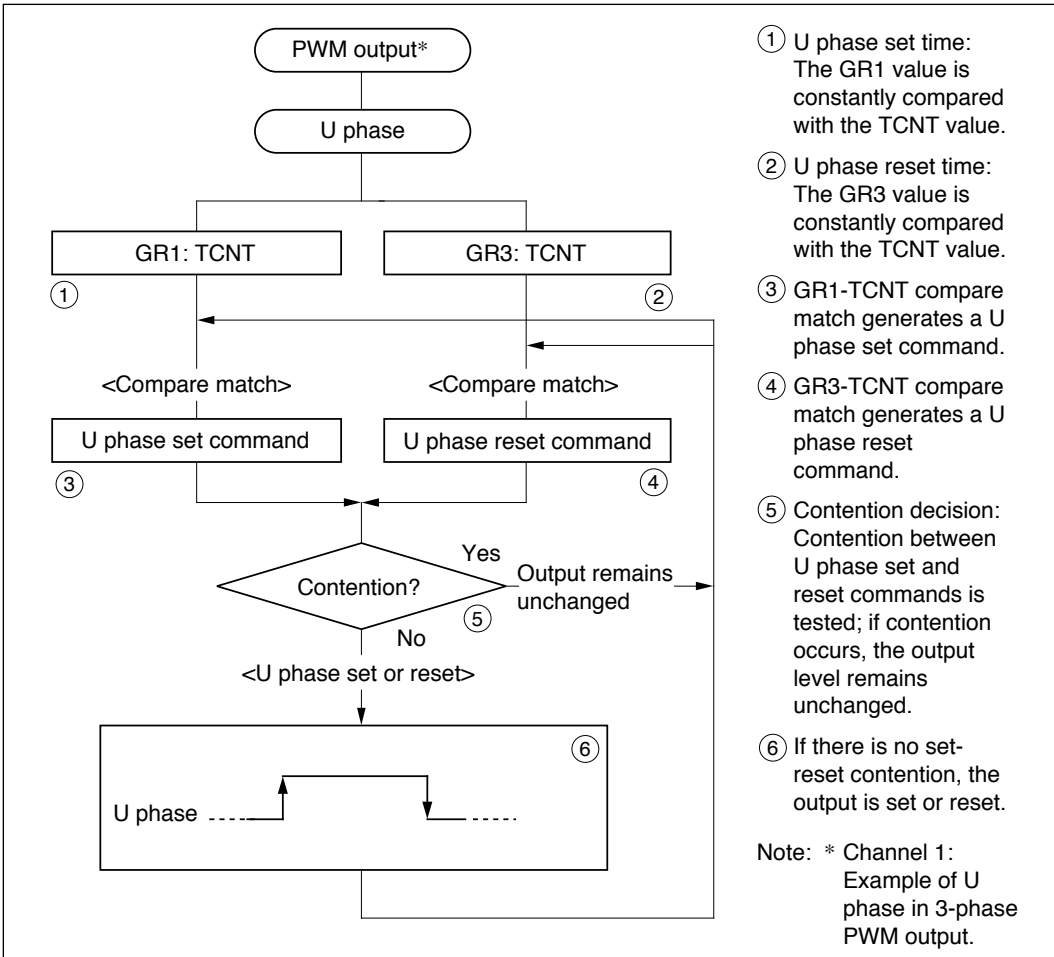

Figure 10-29 PWM Output Operation

Figure 10-30 shows an example of three-phase PWM output on channel 1.

The U phase is output at the T1IOC₁ pin. The V phase is output at the T1IOC₂ pin. The W phase is output at the T1IOC₃ pin. The IPU sets T1IOC₁ when the timer counter matches GR1 (H'0001), and resets T1IOC₁ when the timer counter matches GR3 (H'00FE). The IPU sets T1IOC₂ when the timer counter matches GR2 (H'0002), and resets T1IOC₂ when the timer counter matches GR4 (H'00FD). The IPU sets T1IOC₃ when the timer counter matches DR1 (H'0003), and resets T1IOC₃ when the timer counter matches DR3 (H'00FC).

The IPU clears the counter when the timer counter matches DR4 (H'00FF).

- Settings
 - TMDRB: H'C1 (PWM output on channel 1)
 - TCRL: H'F0 (clear on T1DR4 compare match)
 - TCRA: H'F0

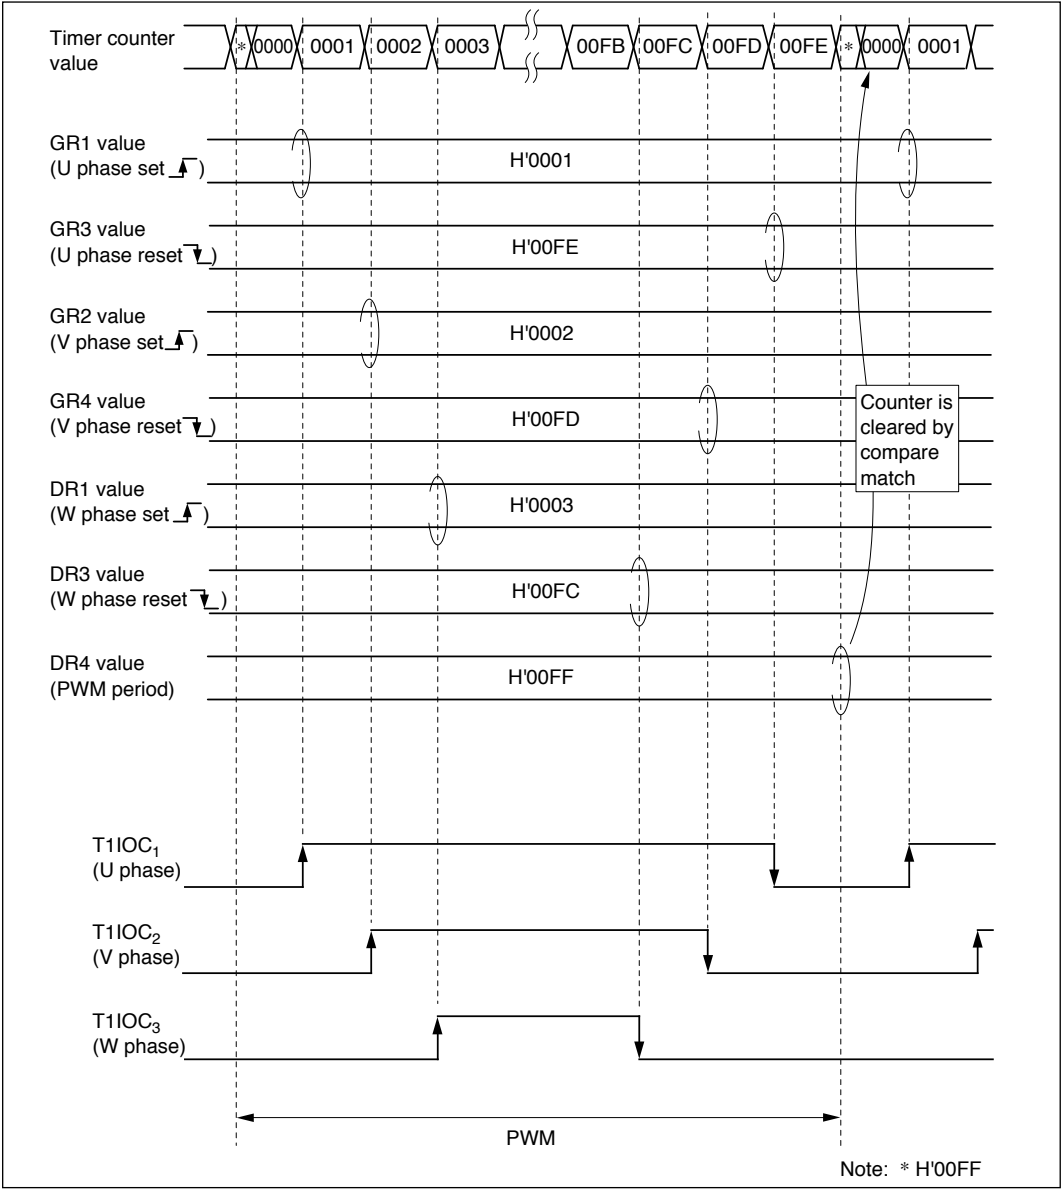

Figure 10-30 Example of Three-Phase PWM Output on Channel 1

In PWM mode the compare registers are paired: one register sets the pulse; the other register resets the pulse. The counter should be set to periodic counting mode. Table 10-7 indicates the register pair assigned to each output pin.

Table 10-7 Output Pins and Register Pairs

Channel	Output Pin	Set	Reset	PWM Period
1	T1IOC ₁	GR1	GR3	DR2, GR3, DR4
	T1IOC ₂	GR2	GR4	
	T1OC ₁	DR1	DR3	
2	T2IOC ₁	GR1	DR1	DR2
	T2IOC ₂	GR2	DR2	
3	T3IOC ₁	GR1	DR1	DR2
	T3IOC ₂	GR2	DR2	
6	T6IOC ₁	GR1	GR2	GR2
7	T7IOC ₁	GR1	GR2	GR2

Usage Notes

1. In PWM output mode, the output levels of PWM output pins cannot be set in the timer output enable register (TOER). Any output level settings made will be ignored.
2. Settings of the IEG bits in timer control register low (TCRL) are valid in PWM output mode. The IEG bits must be cleared to 0.
3. In PWM output mode, periodic counting should be used by selecting a counter clear source in TCRL. Table 10-7 lists the registers that can set the PWM period in each channel.

10.8.6 Synchronizing Mode

In synchronizing mode two or more timer counters can be rewritten or cleared simultaneously. Figure 10-31 shows the procedure for selecting synchronizing mode.

Procedure for Selecting Synchronizing Mode

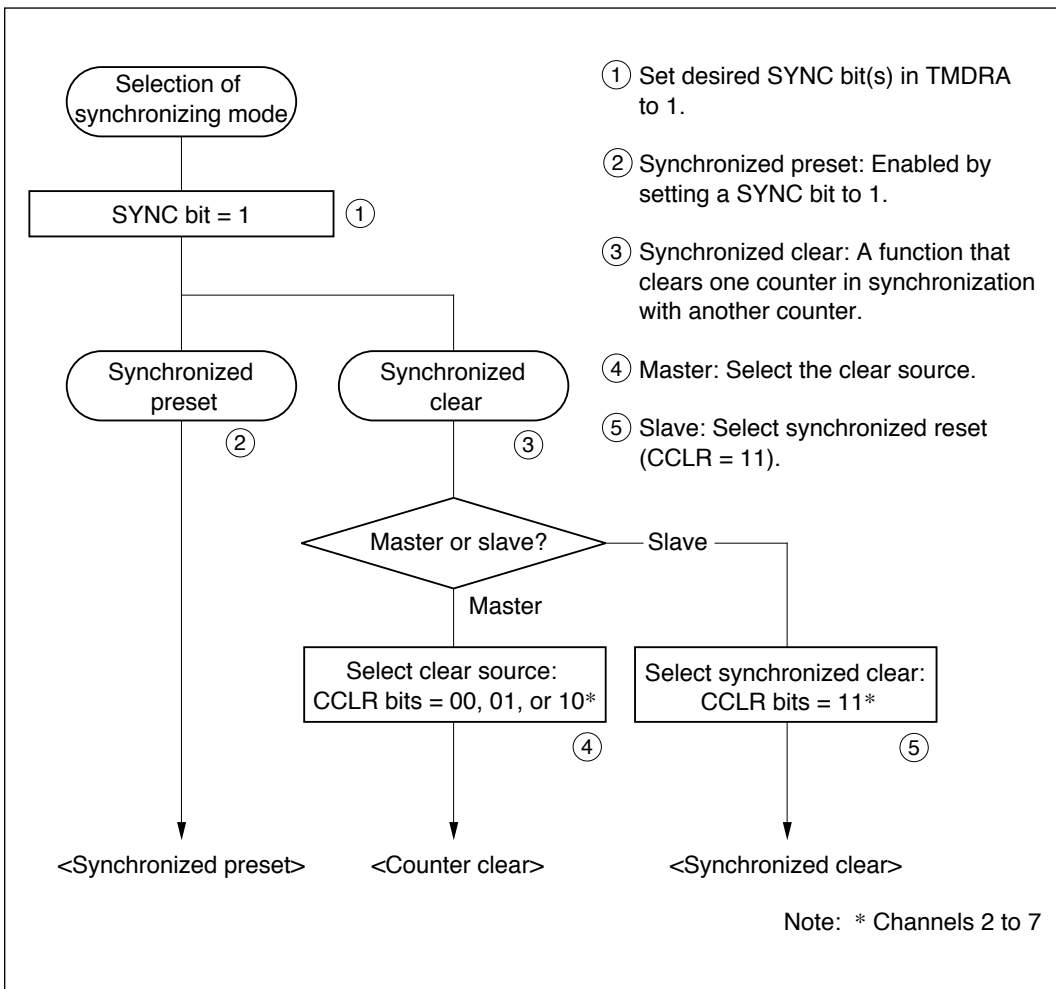

Figure 10-31 Procedure for Selecting Synchronizing Mode

Synchronized Operation: Figure 10-32 shows an example of synchronized operation of channels 2 and 3.

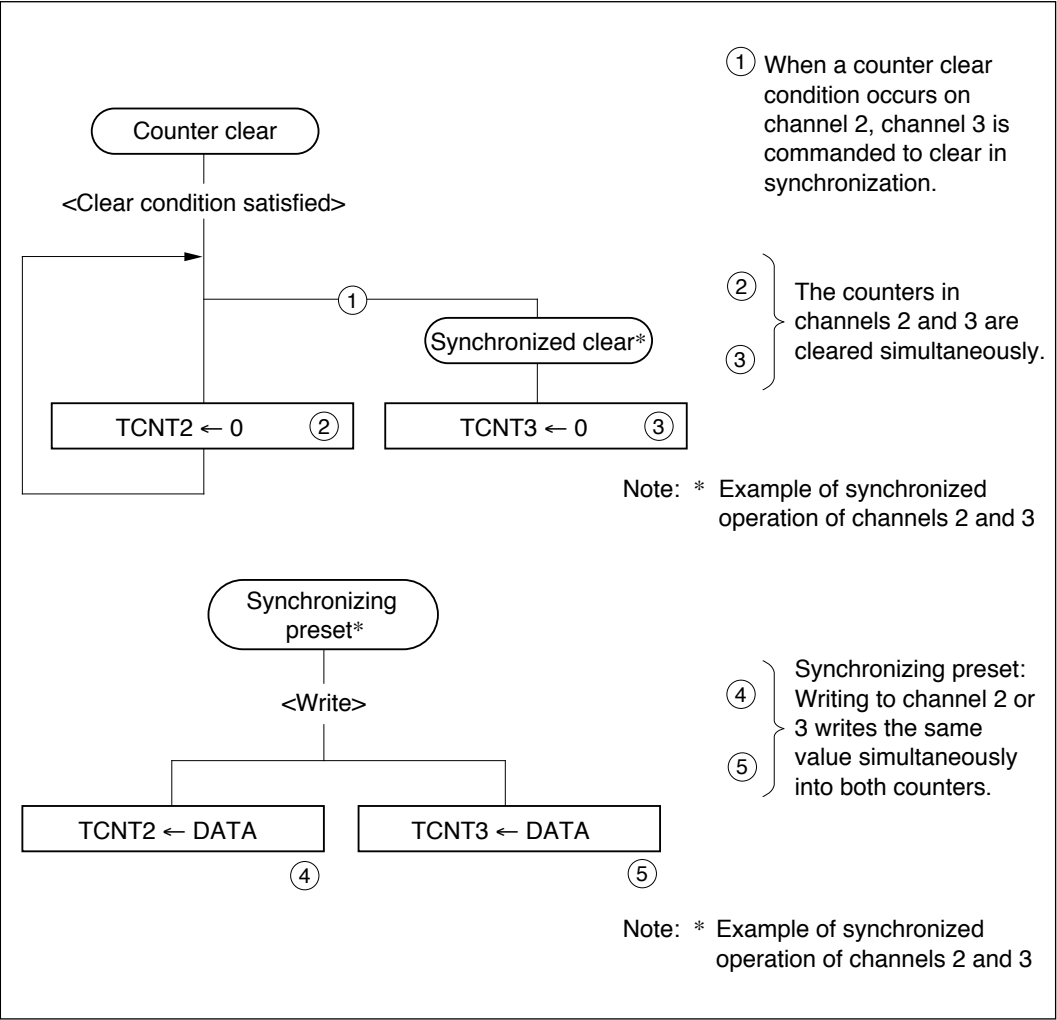

Figure 10-32 Example of Synchronized Operation of Channels 2 and 3

Figure 10-33 shows an example of the synchronization of timer counters 2 and 3.

Timer counters 2 and 3 are synchronized by setting the SYNC1 bit in timer mode register A (TMDRA) to 1. The timer counters are synchronously preset by writing a new value to either timer counter 2 or 3; the IPU simultaneously writes the same value in the other timer counter. Synchronized clearing is selected by setting $CCLR1 = CCLR0 = 1$ as the clear source for timer counter 3. The IPU clears timer counters 2 and 3 simultaneously when timer counter 2 matches T2GR1 (H'00FF).

- Settings

- T2GR1: H'00FF
- TMDRA: H'02 (SYNC1 = 1)
- TCRL (channel 2): H'D0 (clear at compare match with T2GR1)
- TCRL (channel 3): H'F0 (enabling synchronized clearing)

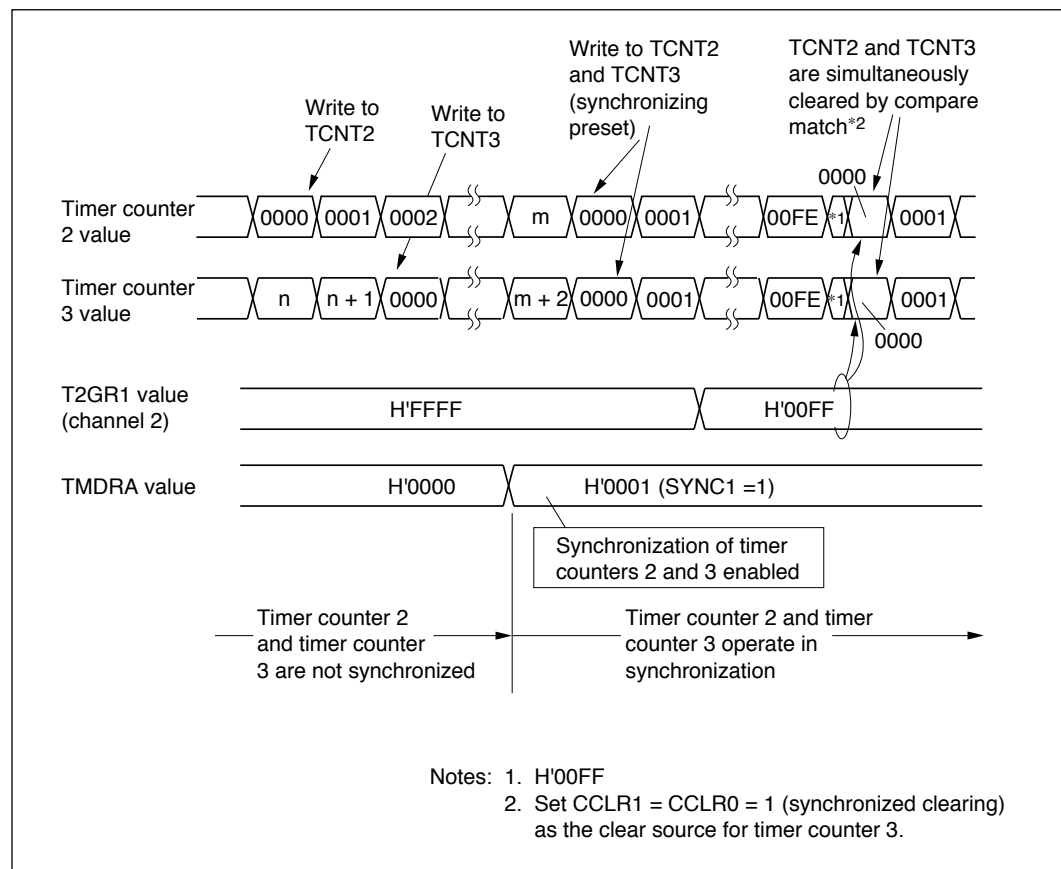

Figure 10-33 Example of Synchronization of Timer Counters 2 and 3

10.8.7 External Event Counting

The IPU has three external clock input pins. If external event signals are input at these external clock input pins, external events can be counted. The counter can be set to increment on the rising or falling edge, or on both edges of the external clock signal. The value of an externally clocked counter can be captured at regular intervals to measure external event frequencies. Figure 10-34 shows the procedure for selecting external event counting mode.

Procedure for Selecting External Event Counting Mode

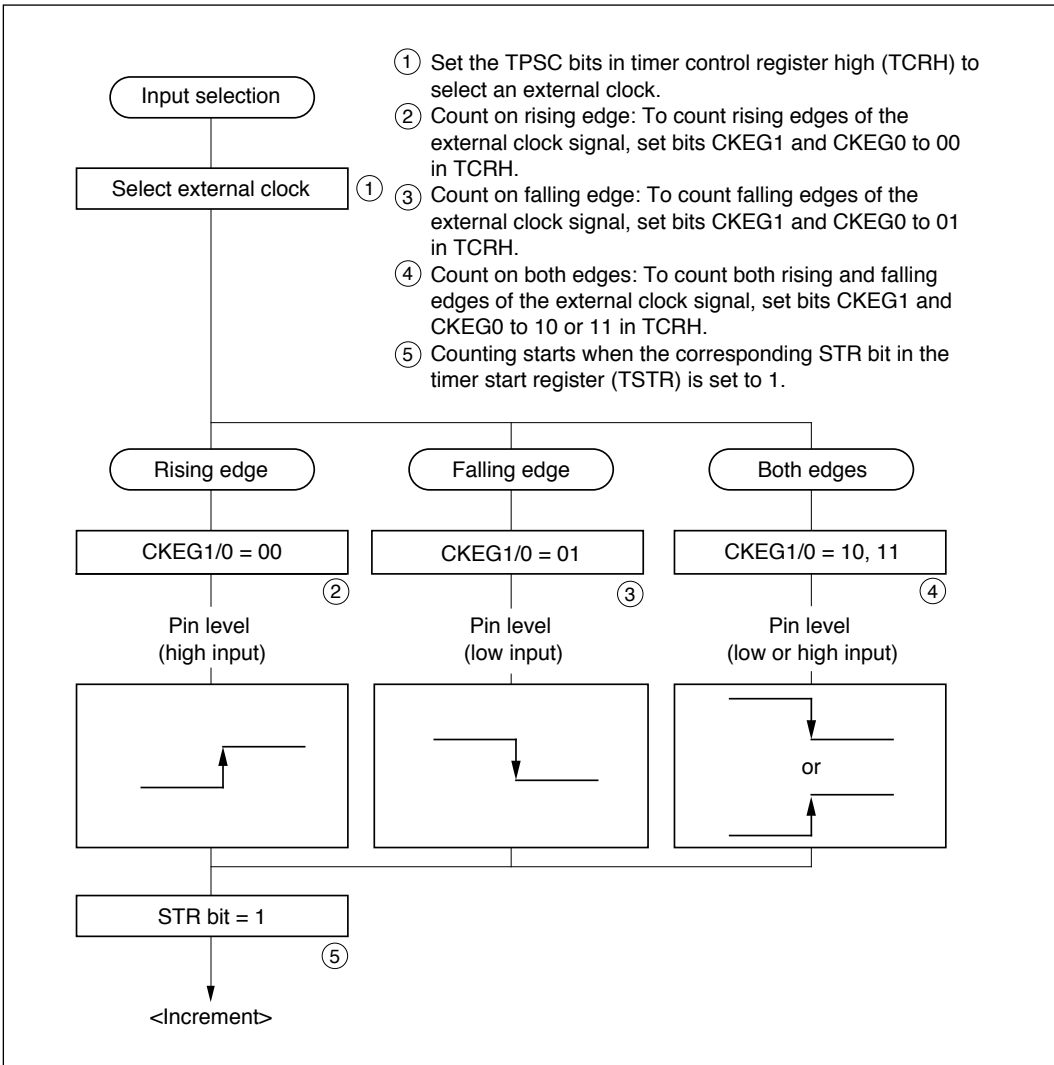

Figure 10-34 Procedure for Selecting External Event Counting Mode

External Event Counting Operation: Counting operations are the same as for an internal clock. For details, see section 10.8.1, “Examples of Counting.”

Figure 10-35 shows an example of external event counting.

In this example timer counters 1, 2, and 3 count external event inputs at $TCLK_1$. In channel 1, the rising edge of $TCLK_1$ is selected by setting the CKEG1 and CKEG0 bits in TCRH to 00. The IPU counts rising edges of $TCLK_1$. In channel 2, the falling edge of $TCLK_1$ is selected by setting the CKEG1 and CKEG0 bits in TCRH to 01. The IPU counts falling edges of $TCLK_1$. In channel 3, both edges of $TCLK_1$ are selected by setting the CKEG1 and CKEG0 bits in TCRH to 10 or 11. The IPU counts both rising and falling edges of $TCLK_1$.

- Settings
 - TCRH (channel 1): H'CD (count rising edges)
 - TCRH (channel 2): H'DD (count falling edges)
 - TCRH (channel 3): H'ED or H'FD (count both rising and falling edges)

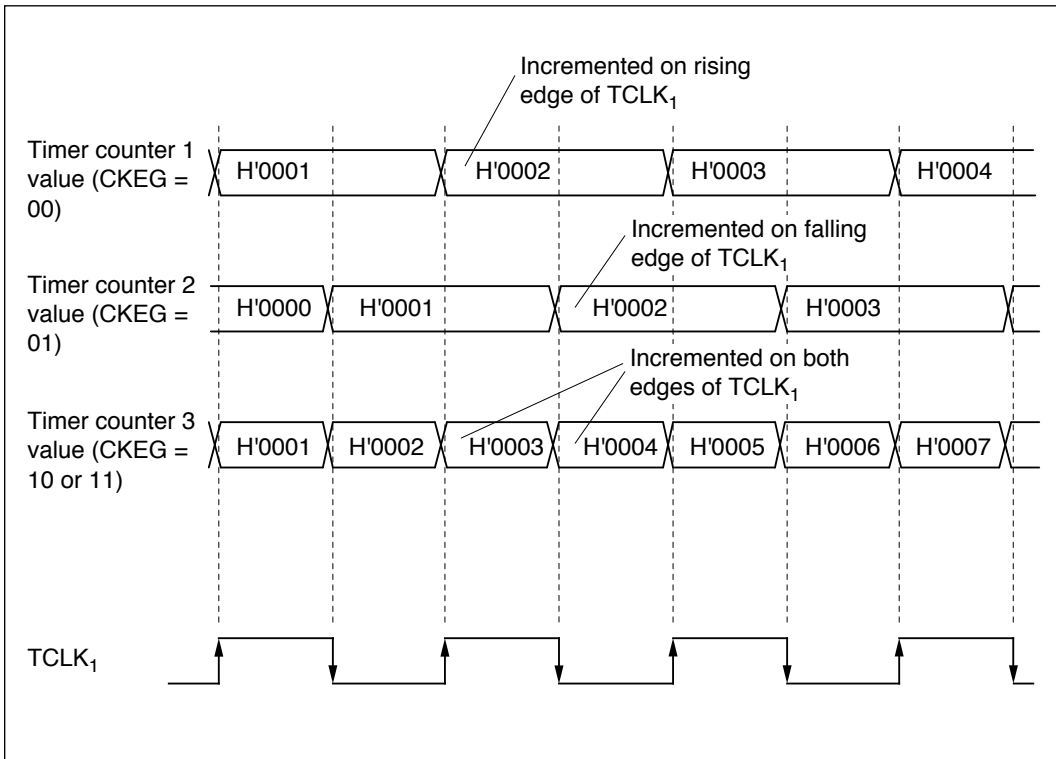

Figure 10-35 Example of External Event Counting

Figure 10-36 shows an example of external clock input timing.

The IPU latches external clock signals ($TCLK_1$ to $TCLK_3$) on the rising edge of the system clock (ϕ). $TCNT2$ is incremented 1.5 system clock cycles ($1.5t_{CYC}$) after the external clock is latched. The pulse width of the external clock signal must be at least $1.5t_{CYC}$.

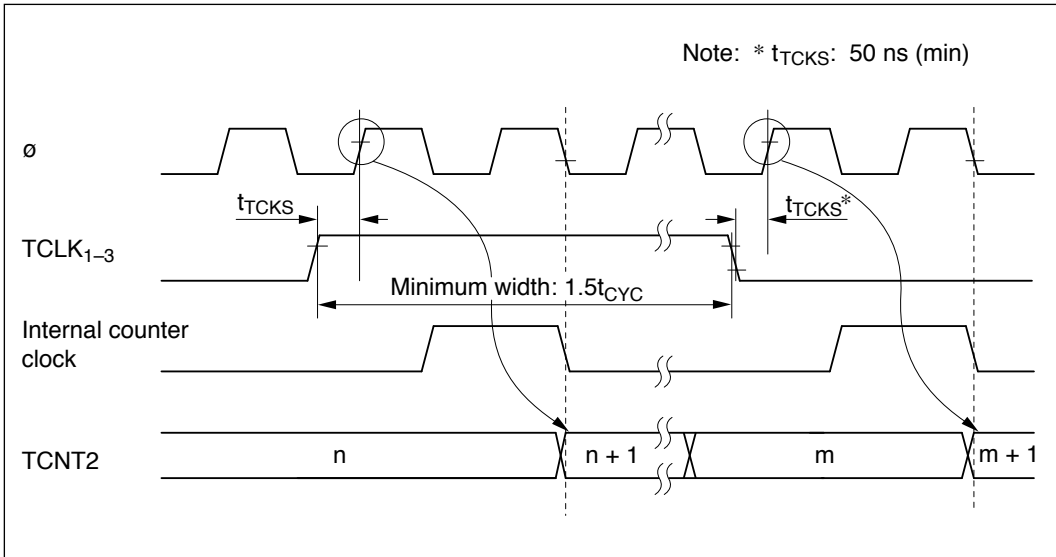

Figure 10-36 External Clock Input Timing

10.8.8 Programmed Periodic Counting Mode

In programmed periodic counting mode, the value of an externally clocked counter is captured into a general register by compare match on a different channel. No external input capture signal is needed. Figure 10-37 shows the procedure for selecting programmed periodic counting mode.

Procedure for Selecting Programmed Periodic Counting Mode

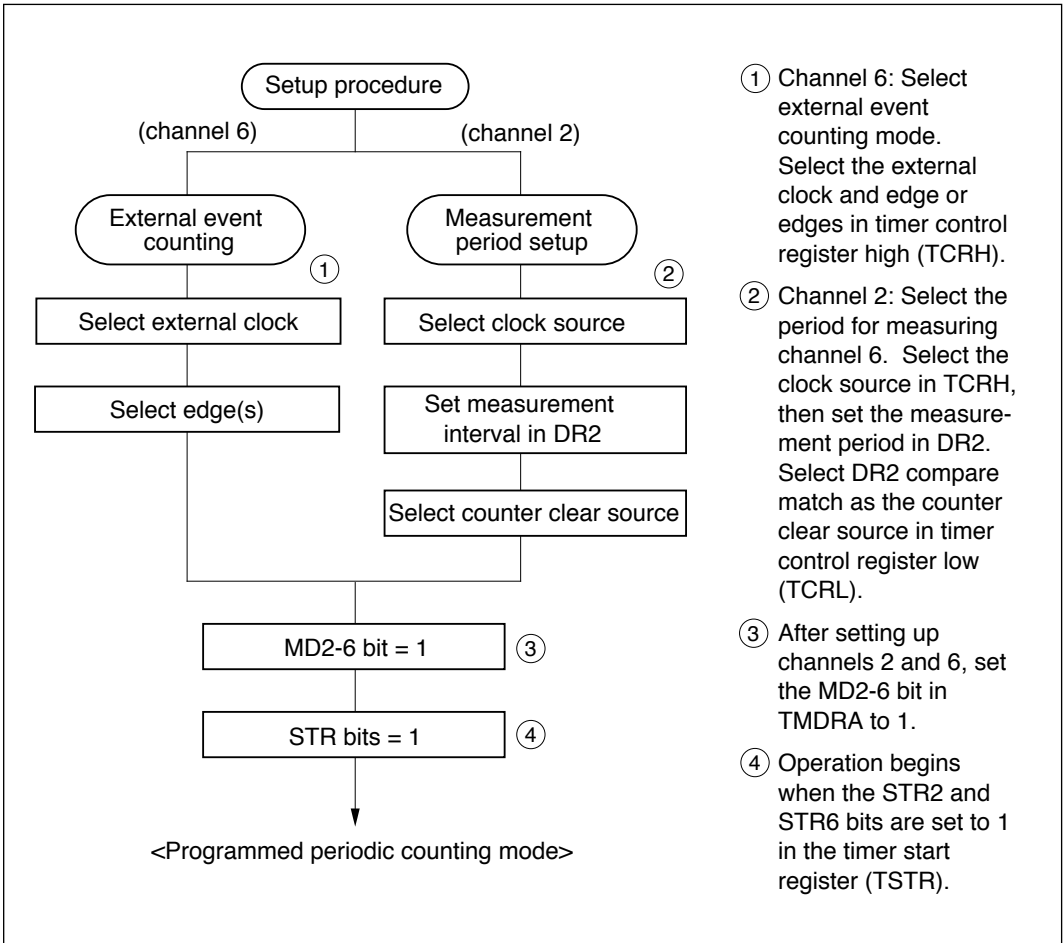

Figure 10-37 Procedure for Selecting Programmed Periodic Counting Mode

Programmed Periodic Counting Operation: Figure 10-38 shows the programmed periodic counting operation.

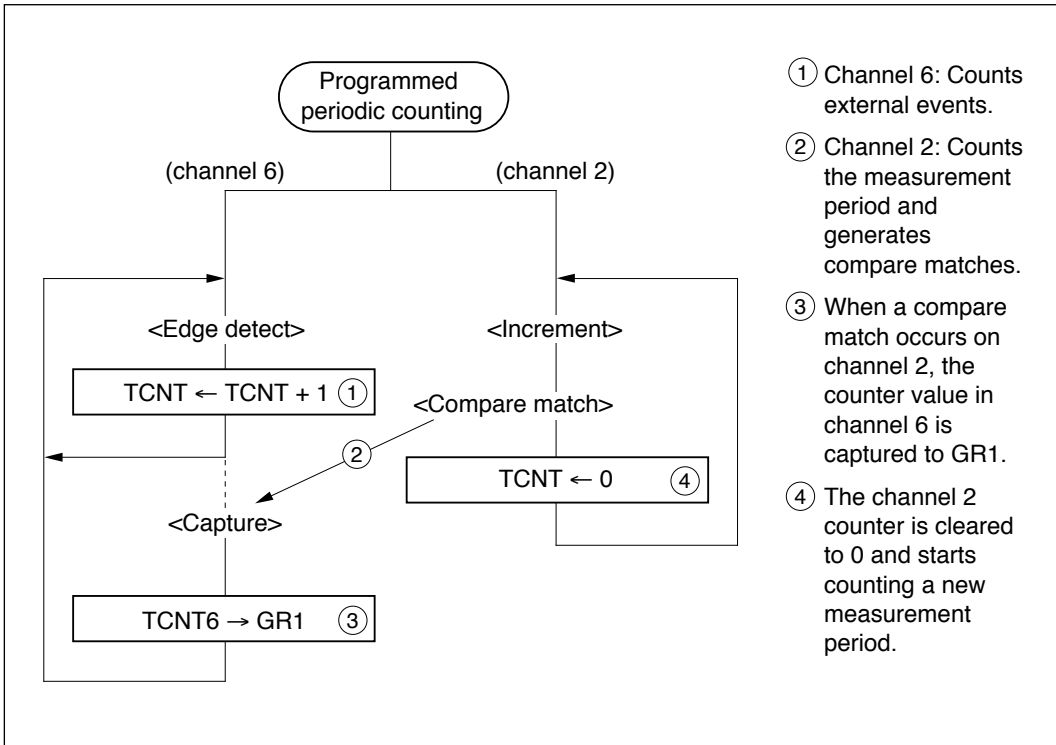

Figure 10-38 Operation in Programmed Periodic Counting Mode

Figure 10-39 shows an example of programmed periodic counting. Table 10-8 lists the possible combinations of compare-match channels and capture channels.

In this example external events are counted over a programmed period using channels 2 and 6. The IPU automatically transfers the value of timer counter 6 (H'0012) to T6GR1 when timer counter 2 matches T2DR2 (H'0100). Timer counter 2 is set to be cleared by compare match with T2DR2.

- Settings
 - TCRL (channel 2): H'E0 (cleared by compare match with T2DR2)
 - TCRH (channel 6): H'ED or H'FD (increment on both rising and falling edges)
 - TMDRA: H'10 (capture to T6GR1 on compare match with T2DR2)

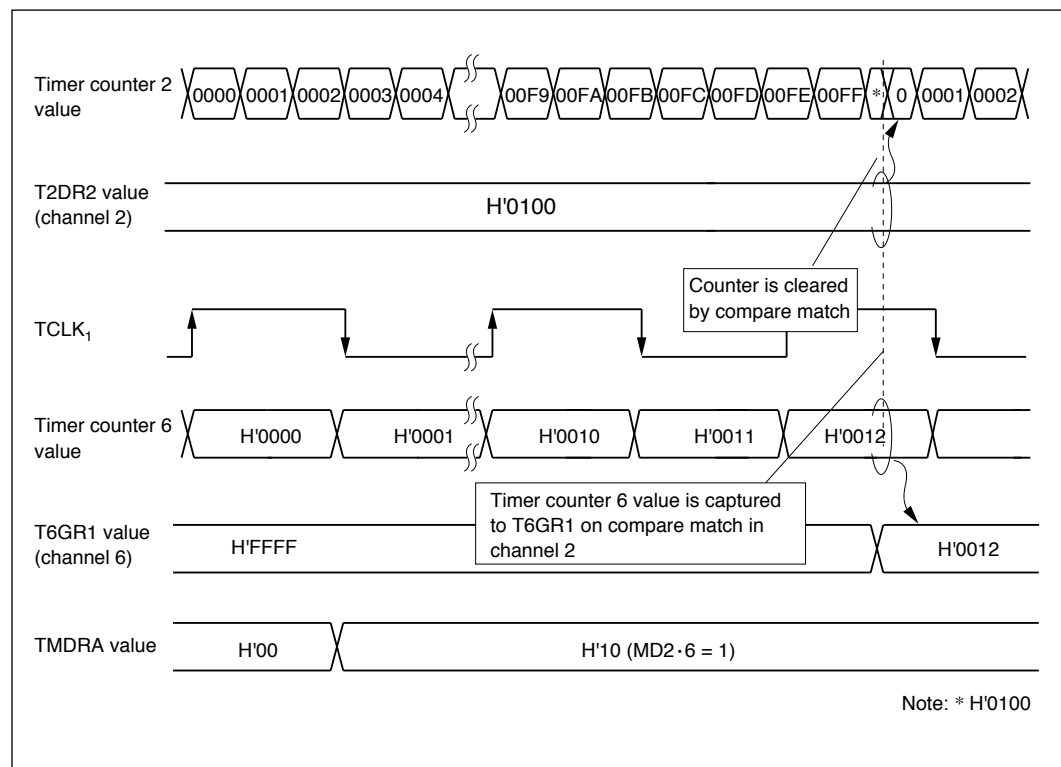

Figure 10-39 Example of Programmed Periodic Counting

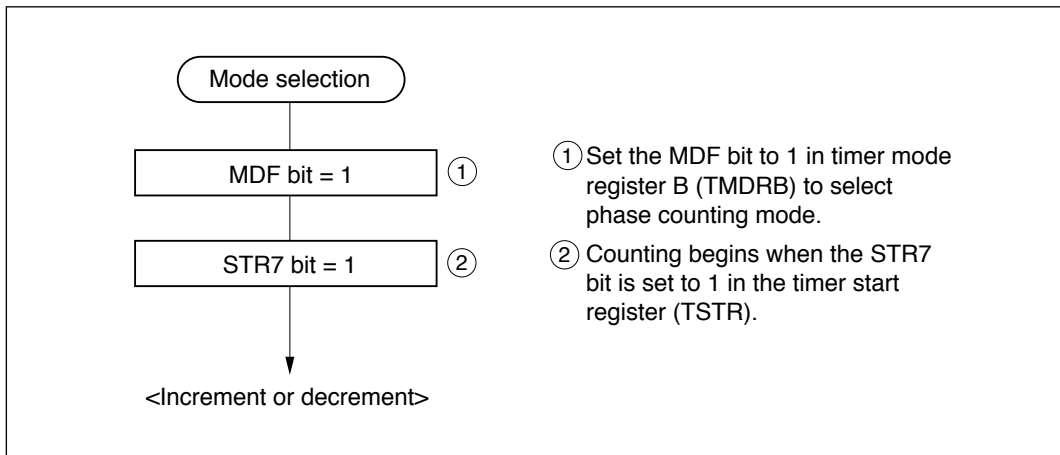

Table 10-8 Combinations of Compare Match Channels and Capture Channels

	Compare Match Channel		Capture Channel	
	Channel No.	Register	Channel No.	Register
MD2·6	Channel 2	DR2	Channel 6	GR1
MD3·5	Channel 3	DR2	Channel 5	GR1
MD4·7	Channel 4	DR2	Channel 7	GR1
MD6·7	Channel 6	GR2	Channel 7	GR2

10.8.9 Phase Counting Mode

One application of phase counting mode is control of an AC servo motor. If the output of a two-phase encoder is fed to two external clock pins, the phase relationship between the two clock signals is detected and the counter is incremented or decremented accordingly. Phase counting is available only on channel 7. Figure 10-40 shows the procedure for selecting phase counting mode.

Procedure for Selecting Phase Counting Mode

**Figure 10-40 Procedure for Selecting Phase Counting Mode**

Phase Counting Operation: Figure 10-41 shows the phase counting operation.

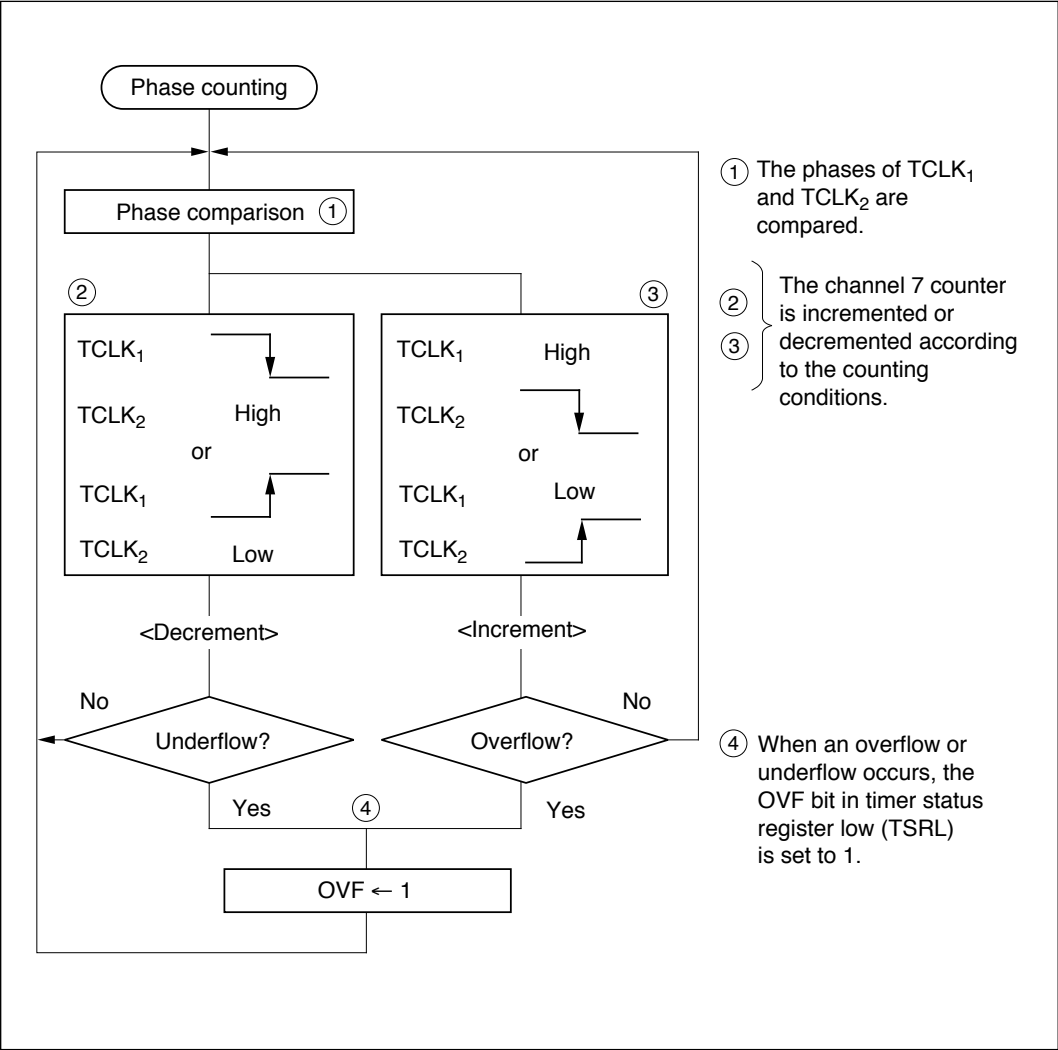

Figure 10-41 Operation in Phase Counting Mode

Figure 10-42 shows an example in which the counter counts up, overflows, then counts down.

In up-counting, the counter counts repeatedly from H'0000 to H'FFFF. The IPU sets the overflow flag (OVF) in timer status register low (TSRL) when the count returns from H'FFFF to H'0000. For the up/down counting conditions, see figure 10-44 “Counting Conditions” and table 10-9 “Up/Down Counting Conditions.”

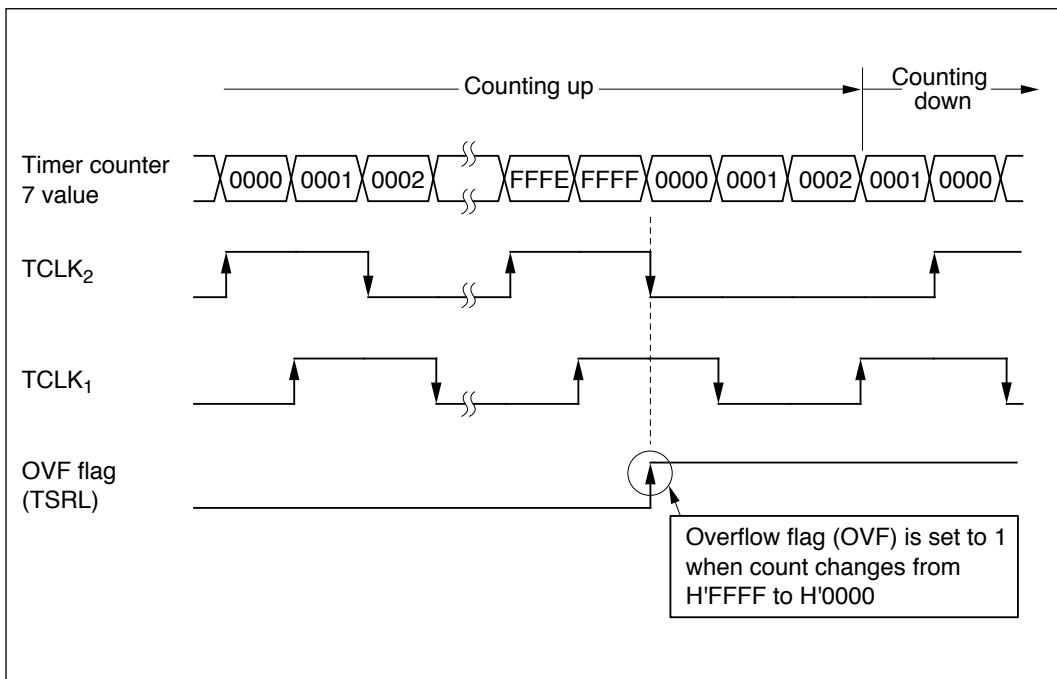

Figure 10-42 Example of Up-Counting, Overflow, and Down-Counting

Figure 10-43 shows an example in which the counter counts down, underflows, then counts up.

In down-counting, the counter counts repeatedly from H'FFFF to H'0000. The IPU sets the overflow flag (OVF) in timer status register low (TSRL) when the count returns from H'0000 to H'FFFF. For the up/down counting conditions, see figure 10-44 “Counting Conditions” and table 10-9, “Up/Down Counting Conditions.”

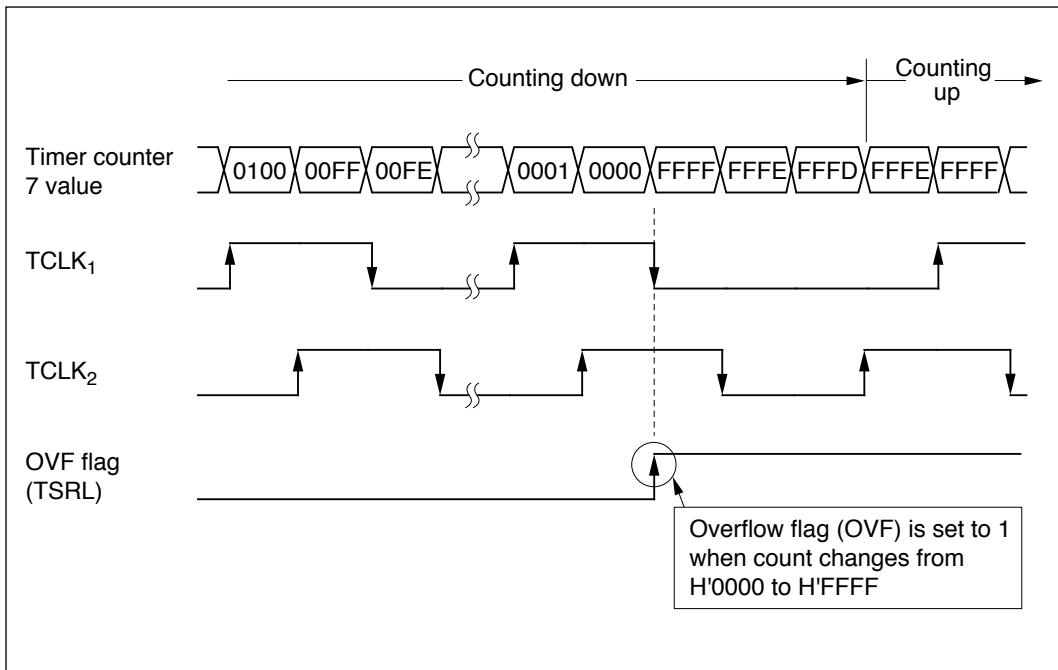

Figure 10-43 Example of Down-Counting, Underflow, and Up-Counting

Figure 10-44 shows the counting conditions. Table 10-9 indicates the up- and down-counting conditions. The IPU counts all edges of $TCLK_1$ and $TCLK_2$.

Figure 10-44 Counting Conditions

Table 10-9 Up/Down Counting Conditions

Counting Direction	Up-Counting				Down-Counting			
$TCLK_2$		High		Low		Low		High
$TCLK_1$	Low		High		High		Low	

Figure 10-45 shows the external clock input timing in phase counting mode.

The IPU latches the external clock signals on the rising edge of the system clock (ϕ). The counter is incremented 1.5 system clock cycles ($1.5t_{CYC}$) after the external clock is latched.

The external clock pulse width must be at least 1.5 system clock cycles ($1.5t_{CYC}$). The phase difference between $TCLK_1$ and $TCLK_2$ must be at least $1.0t_{CYC}$.

Figure 10-45 External Clock Input Timing in Phase Counting Mode

10.9 Interrupts

The IPU can request three types of interrupts: compare match, input capture, and overflow. The timing of each type of interrupt request is described next.

10.9.1 Interrupt Timing

(1) Output Compare Timing: Figure 10-46 shows the timing from counter increment to generation of a compare match interrupt request. One system clock cycle ($1.0t_{CYC}$) after timer counter 2 matches the T2GR1 value (N), the IPU sets the input capture/compare match flag (IMF). A compare match signal ($T2IOC_1$) is output $0.5t_{CYC}$ after IMF is set. The interrupt request ($T2IMI1$) is generated $0.5t_{CYC}$ after the $T2IOC_1$ output. The $T2IMI1$ interrupt request therefore comes $2.0t_{CYC}$ after the counter is incremented to N.

Figure 10-46 Timing from Incrementation to Compare Match Interrupt Request

(2) Input Capture Timing: Figure 10-47 shows the timing from capture signal input to generation of an input capture interrupt request. A maximum $1.5t_{CYC}$ after input of the capture signal, the IPU transfers the timer counter value (N) to T2GR1. The input capture/compare match flag (IMF) is set $0.5t_{CYC}$ after the input capture transfer. The interrupt request (T2IMI1) is generated $1.0t_{CYC}$ after IMF is set. The T2IMI1 interrupt request therefore comes a maximum $3.0t_{CYC}$ after input of the capture signal.

Figure 10-47 Timing from Capture Input to Input Capture Interrupt Request

(3) Overflow Timing: Figure 10-48 shows the timing from counter increment to generation of an overflow interrupt request. When the value of timer counter 2 returns from H'FFFF to H'0000 the IPU sets the overflow flag (OVF). The interrupt request (T2OVI) is generated $1.0t_{CYC}$ after OVF is set.

In phase counting mode, the IPU sets the overflow flag (OVF) when the timer counter value returns from H'0000 to H'FFFF. For usage in phase counting mode, see section 10.8.9 “Phase Counting Mode.”

Figure 10-48 Timing from Counter Incrementation to Overflow Interrupt Request

10.9.2 Interrupt Sources and DTC Interrupts

The IPU has 35 interrupt sources. Of these, the compare match interrupt sources and the compare match/input capture interrupt sources can start the data transfer controller (DTC) to transfer data. Table 10-10 lists the interrupt sources and indicates which can start the DTC.

The exclusive compare match interrupt sources (such as T1CMI1 and T1CMI2) are paired. Both sources in each pair share the same vector. Data transfer should not be enabled for both interrupt sources at the same time.

Table 10-10 Interrupt Sources and DTC Interrupts

Channel	Interrupt Source	Description	DTC Available	Priority Order
1	T1IMI1	GR1 compare match or input capture	Yes	
	T1IMI2	GR2 compare match or input capture	Yes	
	T1CMI1/ T1CMI2	DR1 or DR2 compare match	Yes	
	T1OVI	Timer counter 1 overflow	No	
	T1IMI3	GR3 compare match or input capture	Yes	
	T1IMI4	GR4 compare match or input capture	Yes	
	T1CMI3/ T1CMI4	DR3 or DR4 compare match	Yes	
2	T2IMI1	GR1 compare match or input capture	Yes	
	T2IMI2	GR2 compare match or input capture	Yes	
	T2CMI1/ T2CMI2	DR1 or DR2 compare match	Yes	
	T2OVI	Timer counter 2 overflow	No	
3	T3IMI1	GR1 compare match or input capture	Yes	
	T3IMI2	GR2 compare match or input capture	Yes	
	T3CMI1/ T3CMI2	DR1 or DR2 compare match	Yes	
	T3OVI	Timer counter 3 overflow	No	
4	T4IMI1	GR1 compare match or input capture	Yes	
	T4IMI2	GR2 compare match or input capture	Yes	
	T4CMI1/ T4CMI2	DR1 or DR2 compare match	Yes	
	T4OVI	Timer counter 4 overflow	No	
5	T5IMI1	GR1 compare match or input capture	Yes	
	T5IMI2	GR2 compare match or input capture	Yes	
	T5CMI1/ T5CMI2	DR1 or DR2 compare match	Yes	
	T5OVI	Timer counter 5 overflow	No	
6	T6IMI1	GR1 compare match or input capture	Yes	
	T6IMI2	GR2 compare match or input capture	Yes	
	T6OVI	Timer counter 6 overflow	No	
7	T7IMI1	GR1 compare match or input capture	Yes	
	T7IMI2	GR2 compare match or input capture	Yes	
	T7OVI	Timer counter 7 overflow	No	Low

10.10 Notes and Precautions

This section describes contention between the compare registers and various IPU operations, and other matters requiring special attention.

(1) Contention between Counter Read/Write by the H8/500 CPU and IPU Operations

Contention between Writing to Timer Counter by H8/500 CPU (T_3) and Clearing by Compare Match: Clearing the counter has priority.

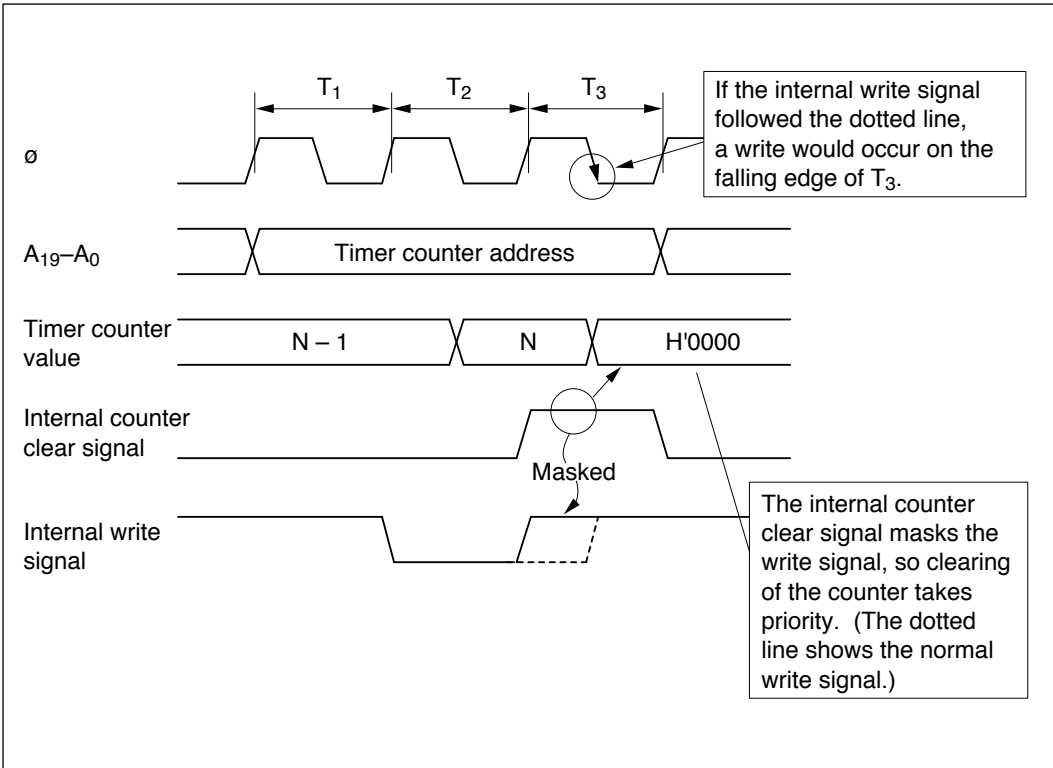

Figure 10-49 Contention between Writing to Timer Counter by H8/500 CPU (T_3) and Clearing by Compare Match

Contention between Writing to Timer Counter by H8/500 CPU (T_3) and Clearing by Capture Input: Clearing the counter has priority.

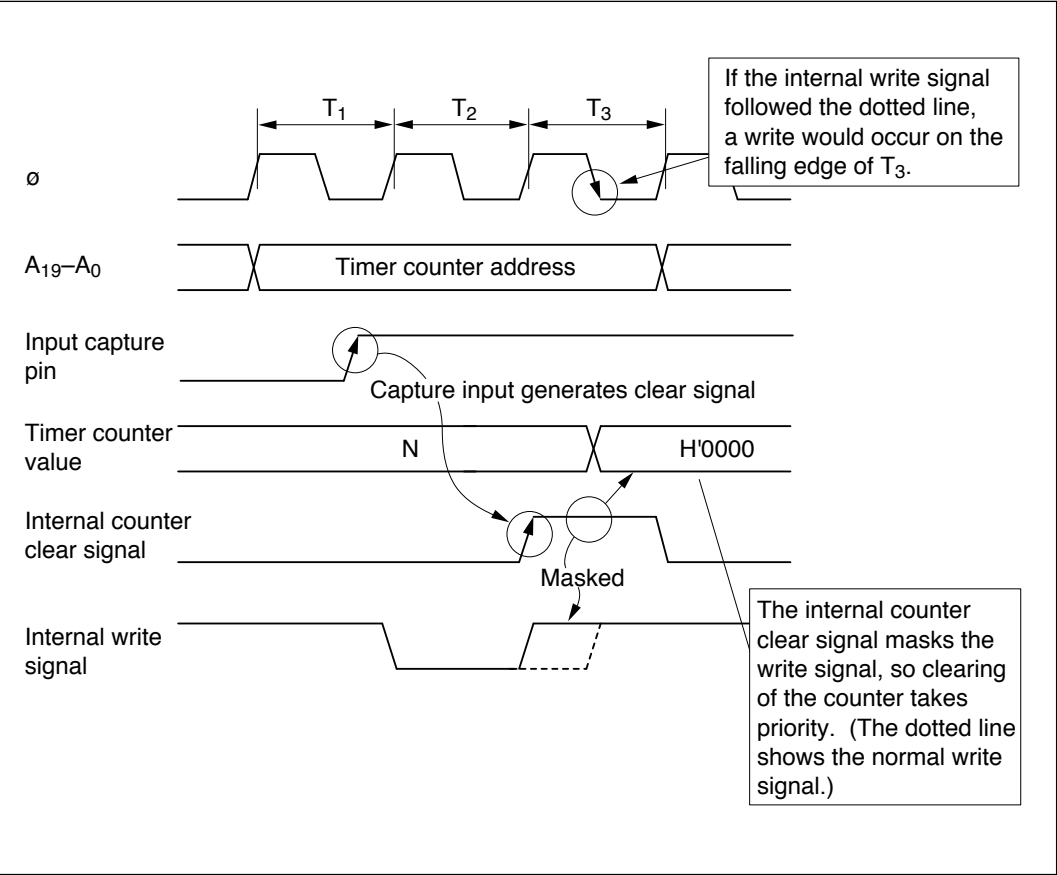

Figure 10-50 Contention between Writing to Timer Counter by H8/500 CPU (T_3) and Clearing by Capture Input

Contention between Timer Counter Write (T_3) and Increment: Writing has priority.

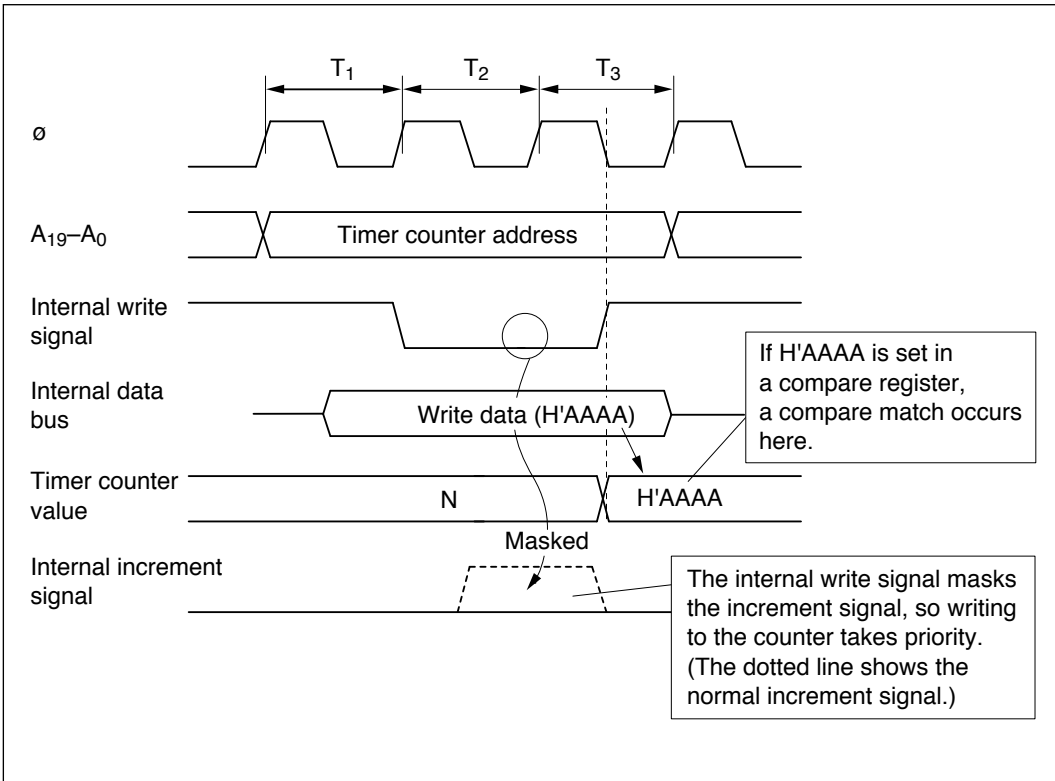

Figure 10-51 Contention between Timer Counter Write (T_3) by H8/500 CPU and Increment

Contention between Timer Counter Write (T₃) and Setting of Overflow Flag: Setting the overflow flag has priority.

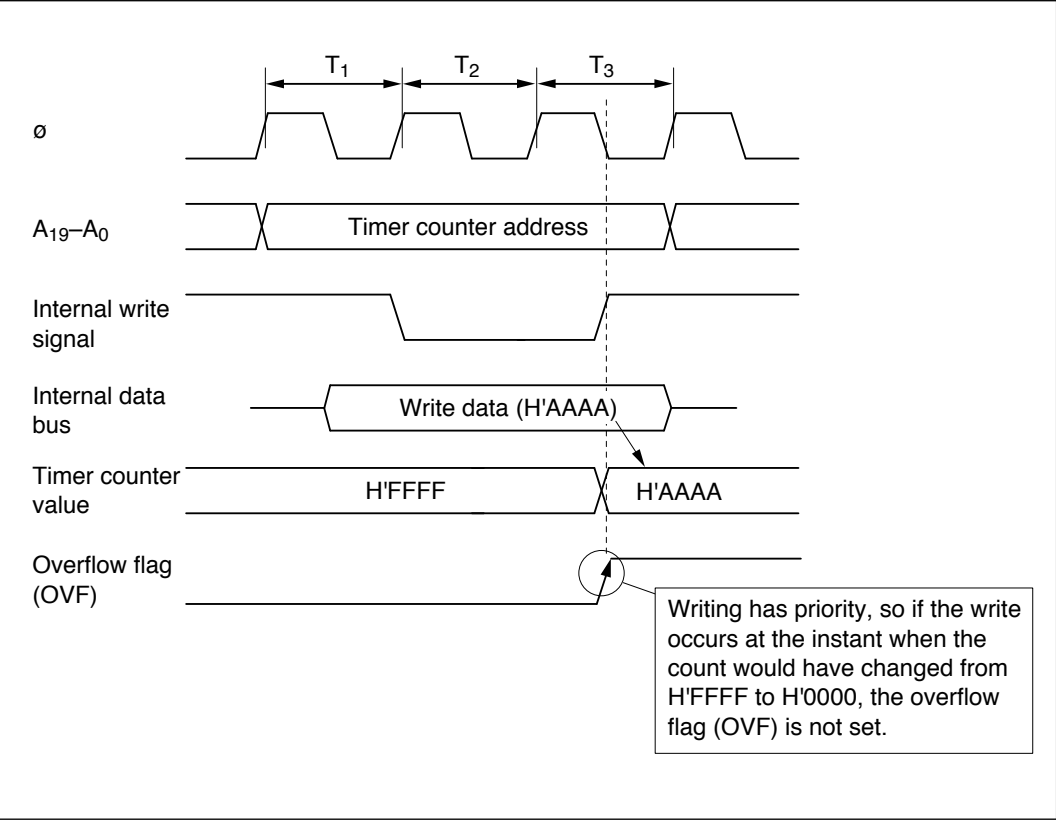

Figure 10-52 Contention between Timer Counter Write (T₃) by H8/500 CPU and Setting of Overflow Flag

Contention between Timer Counter Byte Write (T_2) and Increment: If the write is to the upper byte, the new value is written in the upper byte and the lower byte retains its old value. If the write is to the lower byte, the new value is written in the lower byte and the upper byte retains its old value. If the contention occurs at T_3 , however, the byte that is not written is incremented.

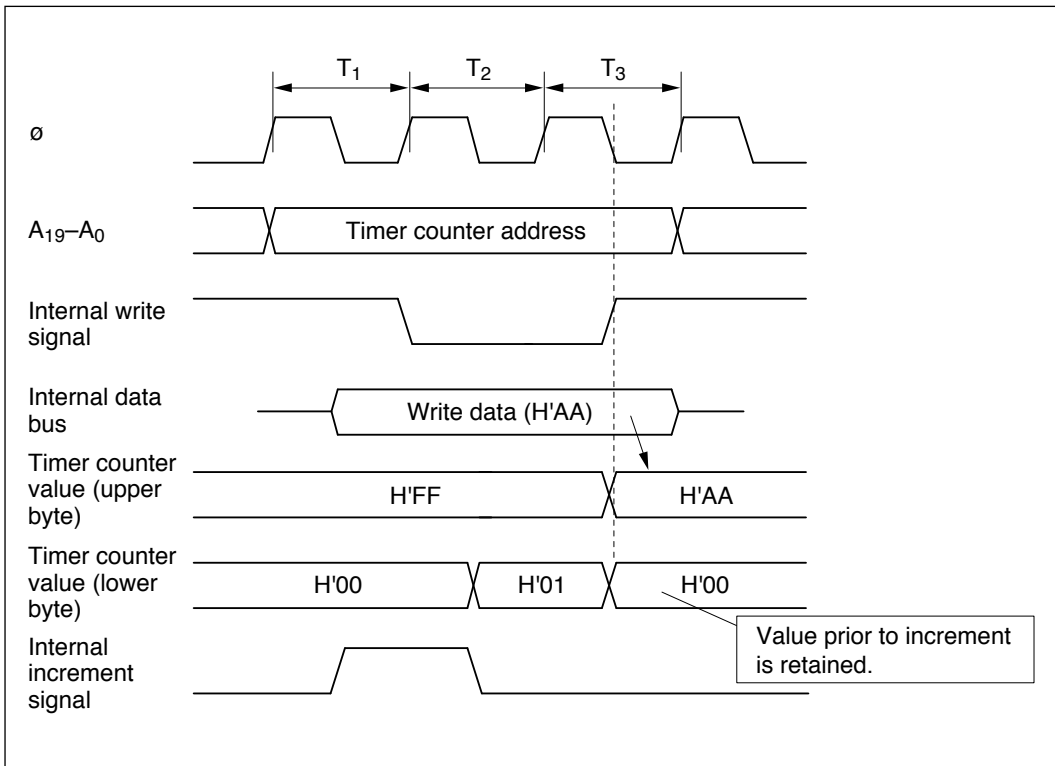

Figure 10-53 Contention between Timer Counter Byte Write (T_2) by H8/500 CPU and Increment

Contention between Capture Register Read (T_3) and Input Capture: The H8/500 CPU reads the data prior to capture.

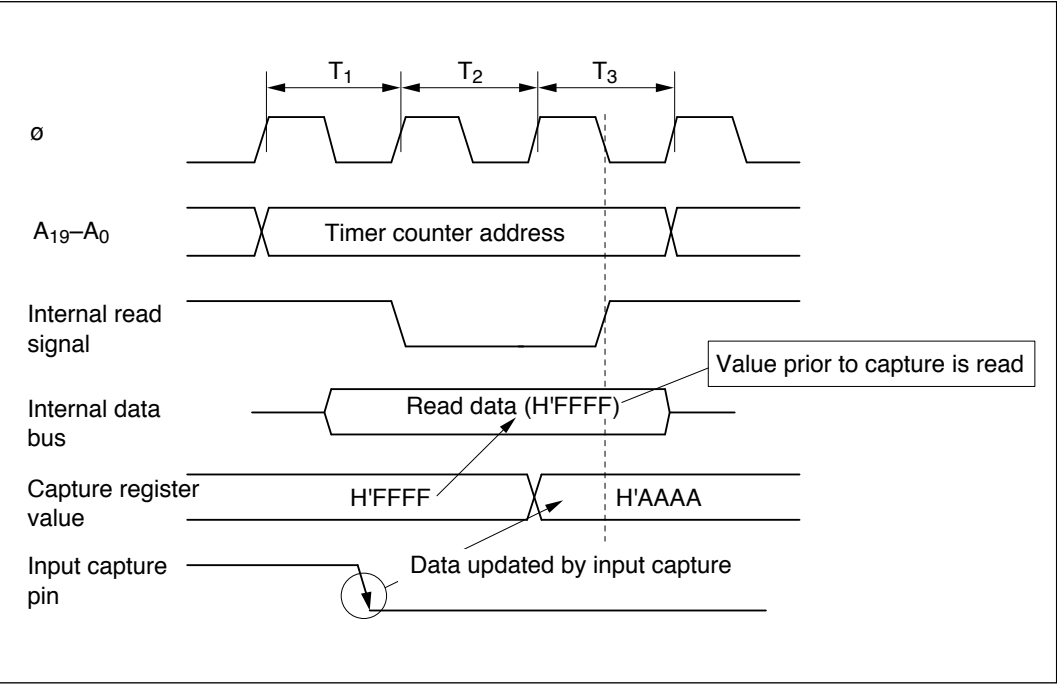

Figure 10-54 Contention between Capture Register Read (T_3) by H8/500 CPU and Input Capture

Contention between Writing to General Register or Dedicated Register by H8/500 CPU (T₃) and Compare Match: Compare match does not occur.

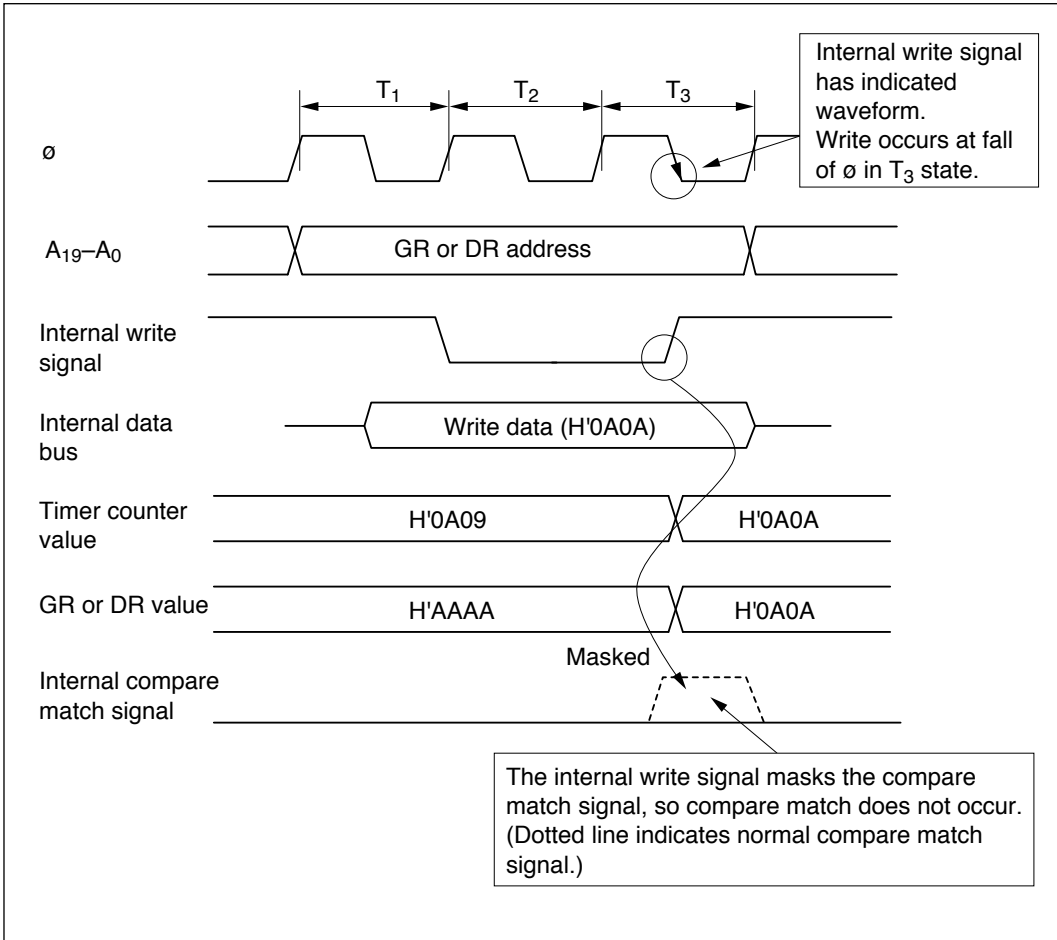

Figure 10-55 Contention between Writing to General Register or Dedicated Register by H8/500 CPU (T₃) and Compare Match

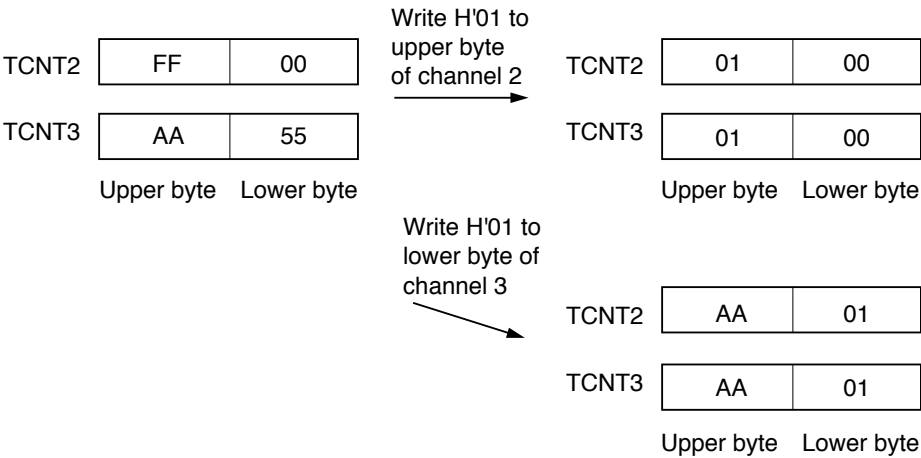

(2) Note on Writing in Synchronizing Mode: After a write in synchronizing mode, all 16 bits of all specified counters have the same value as the counter that was written. This is true regardless of the operand size (word or byte).

Example: When channels 2 and 3 are synchronized

- Word write to channel 2 or word write to channel 3

- Byte write to channel 2 or byte write to channel 3

(3) Note on Compare Register Setting: The compare match frequency differs depending on whether the timer counter clock source is the system clock (ϕ) or another source.

When the counter increments on the system clock as in figure 10-56, the compare match frequency is:

$$T = \phi / (N + 1)$$

(T: compare match frequency. ϕ : system clock frequency. N: value set in compare register.)

When the counter increments on a clock source other than the system clock as in figure 10-57, the compare match frequency is:

$$T = \phi / (D * N) \quad * \text{ Example: If the counter clock source is } \phi/2, \text{ then } D = 2.$$

(T: compare match frequency. ϕ : system clock frequency. D: frequency ratio of system clock to counter clock source. N: value set in compare register.)

In this case, if H'0000 is set in the compare register, compare match does not occur.

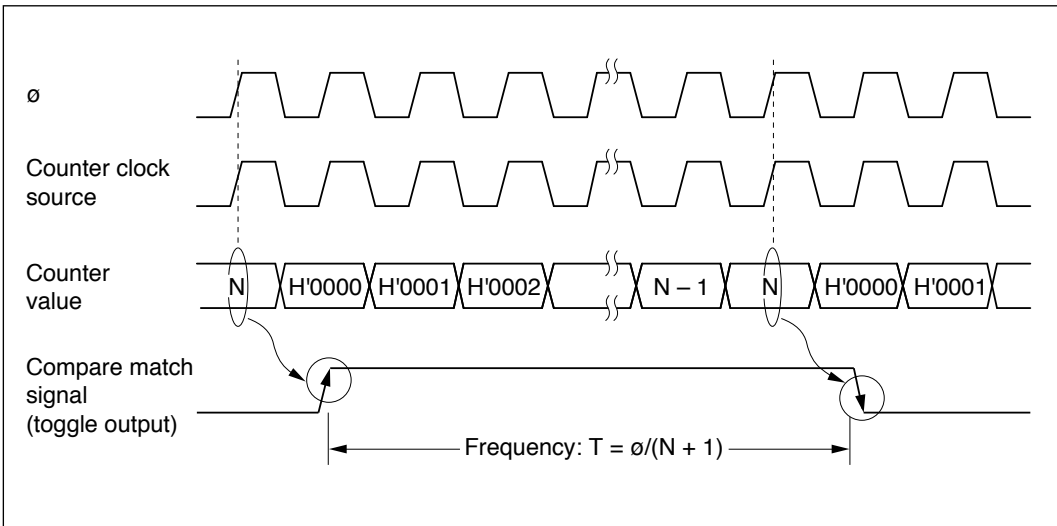

Figure 10-56 Compare Match Frequency when Clock Source is System Clock

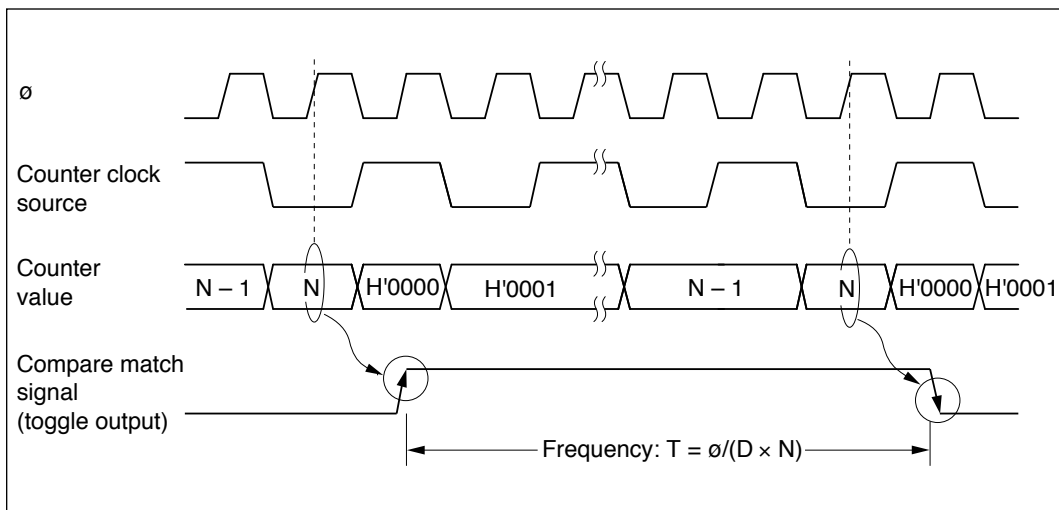

Figure 10-57 Compare Match Frequency when Clock Source is not System Clock

Restriction on Compare Register Updates: When a compare register is updated, no compare match will occur even if the counter value matches the register value. If necessary, before updating the register value, have software check that the following update condition is satisfied (a sample software check routine is shown below).

Update Condition: If a compare match is required in every cycle, as in PWM mode, ensure that the following condition is satisfied so that the register value and counter value will not match during the update.

$$\text{Count} + \text{Disp.} + (\text{Clk} - 1) \neq \text{Reg.}$$

where, Count: Counter value

Disp: Number of cycles from when counter value is read until register write is executed

Clk: Count period of counter

Reg: Register value

The following sample software routine checks the counter value when writing to the register:

- Operating conditions
 - Count period: ϕ
 - Program operating environment: 16-bit-bus, two-state-access area
 - Priority of update process: highest priority

- #CYC: counter operating period

Section 11 Watchdog Timer

11.1 Overview

The H8/538F has one on-chip watchdog timer (WDT) for monitoring system operation. The WDT can generate a reset signal for the entire H8/538F chip if a system crash allows the timer counter (TCNT) to overflow. When this watchdog function is not needed, the WDT can be used as an interval timer. In interval timer operation, an IRQ0 interrupt is requested at each counter overflow. The WDT is also used in recovering from software standby mode.

11.1.1 Features

WDT features are listed below.

- Selection of eight counter clock sources
- Interval timer option
- Timer counter overflow generates a reset signal or interrupt

The reset signal is generated in watchdog timer operation. An IRQ0 interrupt is requested in interval timer operation.

- Overflow reset signal resets the entire H8/538F internally, and can also be output externally

The reset signal generated by timer counter overflow during watchdog timer operation resets the entire H8/538F internally. If enabled by the reset output enable bit, an external reset signal can be output to reset other system devices simultaneously.

11.1.2 Block Diagram

Figure 11-1 shows a block diagram of the WDT.

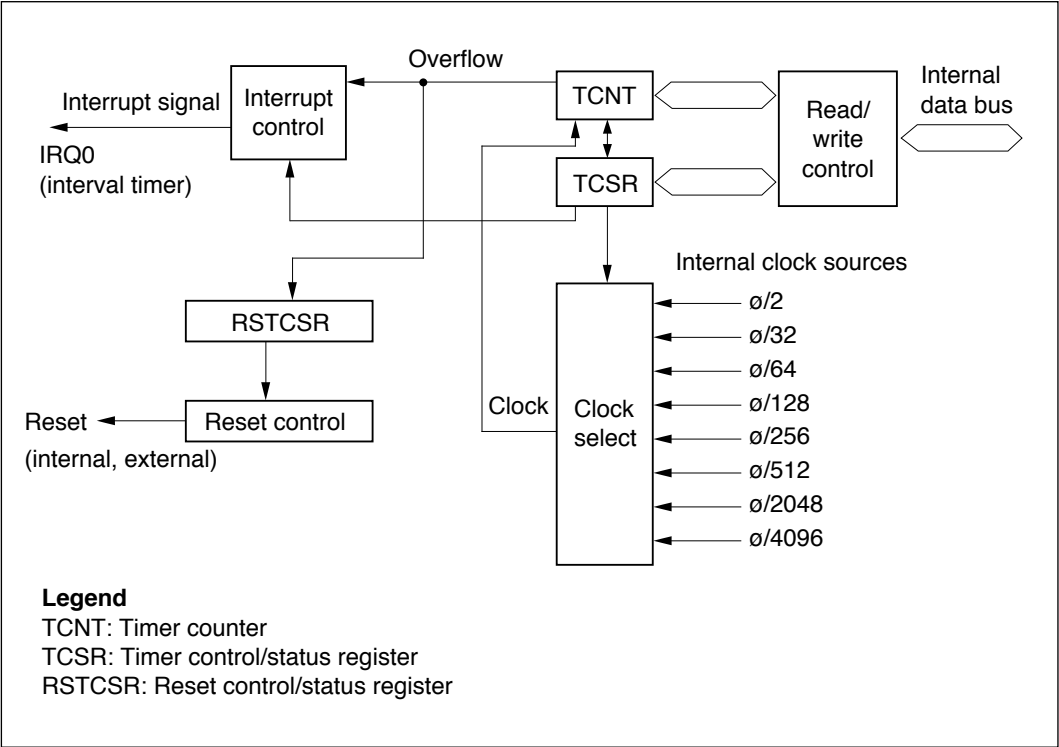

Figure 11-1 WDT Block Diagram

11.1.3 Register Configuration

Table 11-1 summarizes the WDT registers.

Table 11-1 WDT Registers

Address		Name	Abbreviation	R/W	Initial Value
Write	Read				
H'FF10	H'FF10	Timer control/status register	TCSR	R/(W)*	H'18
	H'FF11	Timer counter	TCNT	R/W	H'00
H'FF1F		Reset control/status register	RSTCSR	R/(W)*	H'3F

Note: * Software can write 0 in bit 7 to clear the flag but cannot write 1.

11.2 Register Descriptions

The watchdog timer has three registers, which are described next.

11.2.1 Timer Counter

The timer counter (TCNT) is an eight-bit readable and writable* up-counter. The TCNT bit structure is shown next.

Bit	7	6	5	4	3	2	1	0
Initial value	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

When the timer enable bit (TME) in the timer control/status register (TCSR) is set to 1, the timer counter starts counting pulses of an internal clock source selected by clock select bits 2 to 0 (CKS2 to CKS0) in TCSR. When the count overflows (changes from H'FF to H'00), an overflow flag (OVF) in TCSR is set to 1. The timer count is initialized to H'00 by a reset and when the TME bit is cleared to 0.

Note: * TCNT is write-protected by a password. See section 11.2.4, “Notes on Register Access” for details.

11.2.2 Timer Control/Status Register

The timer control/status register (TCSR) is an eight-bit readable and partly writable*¹ register. Its functions include selecting the timer mode and clock source. The TCSR bit structure is shown next.

Bit	7	6	5	4	3	2	1	0
	OVF	WT/IT	TME	—	—	CKS2	CKS1	CKS0
Initial value	0	0	0	1	1	0	0	0
R/W	R/(W)*2	R/W	R/W	—	—	R/W	R/W	R/W

Overflow flag
Status flag indicating overflow

Timer mode select bit
Selects the mode

Timer enable bit
Enables and disables the timer

Reserved bits

Clock select bits
These bits select the TCNT clock source

Bits 7 to 5 are initialized to 0 by a reset, in hardware standby mode, and in software standby mode. Bits 2 to 0 are initialized to 0 by a reset and in hardware standby mode, but retain their values in software standby mode.

- Notes:
1. TCSR is write-protected by a password. See section 11.2.4 “Notes on Register Access” for details.
 2. Software can write 0 in bit 7 to clear the flag, but cannot set this bit to 1.

(1) Bit 7—Overflow Flag (OVF): This status flag indicates that the timer counter has overflowed from H'FF to H'00 in interval timer mode. When OVF = 1, an IRQ0 interrupt is requested.

Bit 7	
OVF	Description
0	Cleared by reading OVF after it has been set to 1, then writing 0 in OVF (Initial value)
1	Set when TCNT over flows

(2) Bit 6—Timer Mode Select (WT/IT): Selects whether to use the WDT as a watchdog timer or interval timer. If used as an interval timer (WT/IT = 0), the WDT generates an IRQ0 interrupt request when the timer counter (TCNT) overflows. If used as a watchdog timer (WT/IT = 1), the WDT generates a reset when the timer counter (TCNT) overflows.

Bit 6

WT/IT	Description
0	Interval timer: IRQ0 interrupt request (Initial value)
1	Watchdog timer: reset request

(3) Bit 5—Timer Enable (TME): Enables or disables the timer counter (TCNT). Always clear TME to 0 before entering software standby mode.

Bit 5

TME	Description
0	Timer disabled: TCNT is initialized to H'00 and stopped. (Initial value)
1	Timer enabled: TCNT starts counting.

(4) Bits 4 and 3—Reserved: Read-only bits, always read as 1.

(5) Bits 2 to 0—Clock Select 2 to 0 (CKS2/1/0): These bits select one of eight internal clock sources for input to TCNT. The clock signals are obtained by prescaling the system clock (ϕ). The overflow interval listed in the following table is the time from when TCNT begins counting from H'00 until an overflow occurs. When the WDT operates as an interval timer, IRQ0 interrupts are requested at this interval. Set CKS2 to CKS0 to the clock settling time before entering software standby mode.

Bit 2	Bit 1	Bit 0	Description
CKS2	CKS1	CKS0	Clock Source Overflow Interval (ϕ = 10 MHz)
0	0	0	$\phi/2$ 51.2 μ s (Initial value)
0	0	1	$\phi/32$ 819.2 μ s
0	1	0	$\phi/64$ 1.6 ms
0	1	1	$\phi/128$ 3.3 ms
1	0	0	$\phi/256$ 6.6 ms
1	0	1	$\phi/512$ 13.1 ms
1	1	0	$\phi/2048$ 52.4 ms
1	1	1	$\phi/4096$ 104.9 ms

11.2.3 Reset Control/Status Register

The reset control/status register (RSTCSR) is an eight-bit readable and partly writable*1 register that indicates when a reset signal has been generated by WDT overflow, and controls external output of this reset signal.

Bit	7	6	5	4	3	2	1	0
	WRST	RSTOE	—	—	—	—	—	—
Initial value	0	0	1	1	1	1	1	1
R/W	R/(W)*2	R/W	—	—	—	—	—	—

Reserved bits

Reset output enable bit
Enables or disables external reset signal output

Watchdog timer reset bit
Indicates reset occurrence

Bits 7 and 6 are initialized by input of a reset signal at the $\overline{\text{RES}}$ pin. They are not initialized by a reset signal generated by the WDT.

- Notes:
- 1. TCSR is write-protected by a password. See section 11.2.4, “Notes on Register Access” for details
 - 2. Software can write 0 in bit 7 to clear the flag, but cannot set this bit to 1.

(1) Bit 7—Watchdog Timer Reset (WRST): Indicates that the watchdog timer counter has overflowed and generated a reset signal. This reset signal resets the entire H8/538F chip. If the reset output enable bit (RSTOE) is set to 1, the reset signal is also output (low) at the $\overline{\text{RESO}}$ pin to initialize external system devices.

Bit 7	
WRST	Description
0	Cleared to 0 by reset signal input at $\overline{\text{RES}}$ pin, or by software (Initial value)
1	Set by TCNT overflow when WDT is used as a watchdog timer, generating a reset signal

(2) **Bit 6—Reset Output Enable (RSTOE):** Enables or disables external output at the $\overline{\text{RESO}}$ pin of the reset signal generated if the timer counter (TCNT) overflows when the WDT is used as a watchdog timer.

Bit 6

RSTOE	Description
0	Reset signal generated by TCNT overflow is not output externally (Initial value)
1	Reset signal generated by TCNT overflow is output externally

(3) **Bits 5 to 0—Reserved:** Read-only bits, always read as 1.

11.2.4 Notes on Register Access

The watchdog timer’s TCNT, TCSR, and RSTCSR registers differ from other registers in being more difficult to write. The procedures for writing and reading these registers are given below.

(1) **Writing to TCNT and TCSR:** These registers must be written by word access. They cannot be written by byte instructions. Figure 11-2 shows the format of data written to TCNT and TCSR. TCNT and TCSR both have the same write address. The write data must be contained in the lower byte of the written word. The upper byte must contain H'5A (password for TCNT) or H'A5 (password for TCSR). This transfers the write data from the lower byte to TCNT or TCSR.

Figure 11-2 Format of Data Written to TCNT and TCSR

(2) Writing to RSTCSR: RSTCSR must be written by word access. It cannot be written by byte instructions. Figure 11-3 shows the format of data written to RSTCSR. To write 0 in the WRST bit, the write data must have H'A5 in the upper byte and H'00 in the lower byte. The H'00 in the lower byte clears the WRST bit in RSTCSR to 0. To write to the RSTOE bit, the upper byte must contain H'5A and the lower byte must contain the write data. Writing this word transfers a write data value into the RSTOE bit.

Figure 11-3 Format of Data Written to RSTCSR

(3) Reading TCNT, TCSR, and RSTCSR: These registers are read like other registers. Byte access instructions can be used. The read addresses are H'FF10 for TCSR, H'FF11 for TCNT, and H'FF1F for RSTCSR, as listed in table 11-2.

Table 11-2 Read Addresses of TCNT, TCSR, and RSTCSR

Address	Register
H'FF10	TCSR
H'FF11	TCNT
H'FF1F	RSTCSR

11.3 Operation

This section describes operations when the WDT is used as a watchdog timer and as an interval timer, and the WDT's function in software standby mode.

11.3.1 Watchdog Timer Operation

Figure 11-4 illustrates watchdog timer operation. To use the WDT as a watchdog timer, set the $\overline{WT}/\overline{IT}$ and TME bits to 1. Software must prevent TCNT overflow by rewriting the TCNT value (normally by writing H'00) before overflow occurs. If TCNT fails to be rewritten and overflows due to a system crash etc., the H8/538F is internally reset for 518 system clock cycles (518 ϕ).

The watchdog reset signal can be externally output from the \overline{RESO} pin to reset external system devices. The reset signal is output externally for 132 system clock cycles (132 ϕ). External output can be enabled or disabled by the RSTOE bit in RSTCSR.

A watchdog reset has the same vector as a reset generated by input at the \overline{RES} pin. Software can distinguish a \overline{RES} reset from a watchdog reset by checking the WRST bit in RSTCSR.

If a \overline{RES} reset and a watchdog reset occur simultaneously, the \overline{RES} reset always takes priority.

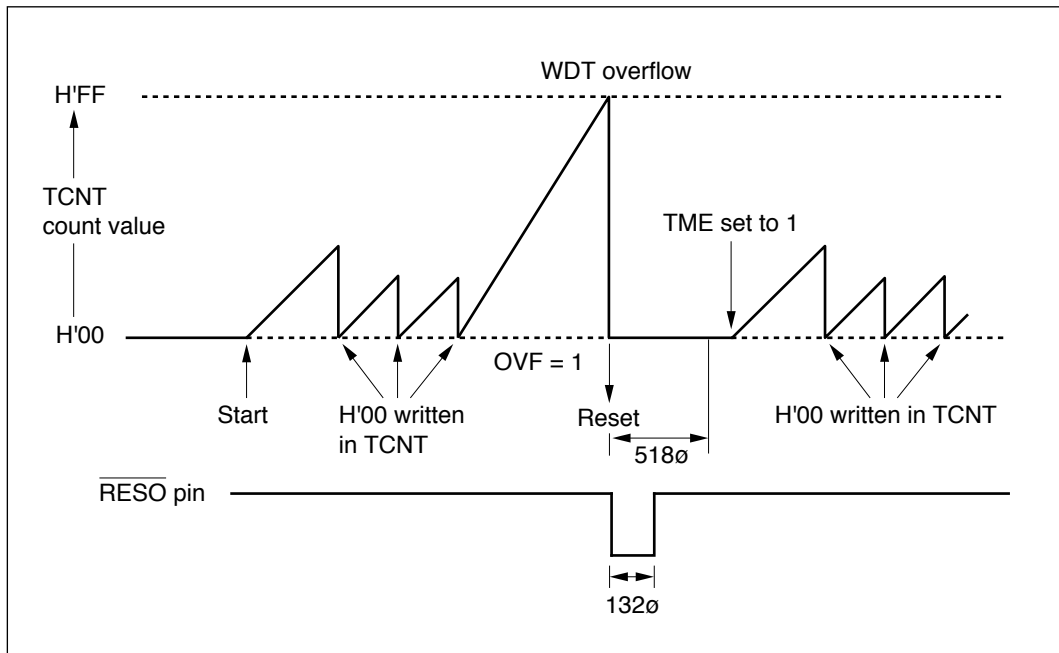

Figure 11-4 Watchdog Timer Operation

11.3.2 Interval Timer Operation

Figure 11-5 illustrates interval timer operation. To use the WDT as an interval timer, clear $\overline{\text{WT/IT}}$ to 0 and set TME to 1. An IRQ0 request is generated each time the timer count overflows. This function can be used to generate IRQ0 requests at regular intervals.

This IRQ0 interrupt has a different vector from the interrupt requested by $\overline{\text{IRQ}_0}$ input. Software does not have to check whether the interrupt request came from the $\overline{\text{IRQ}_0}$ pin or the interval timer.

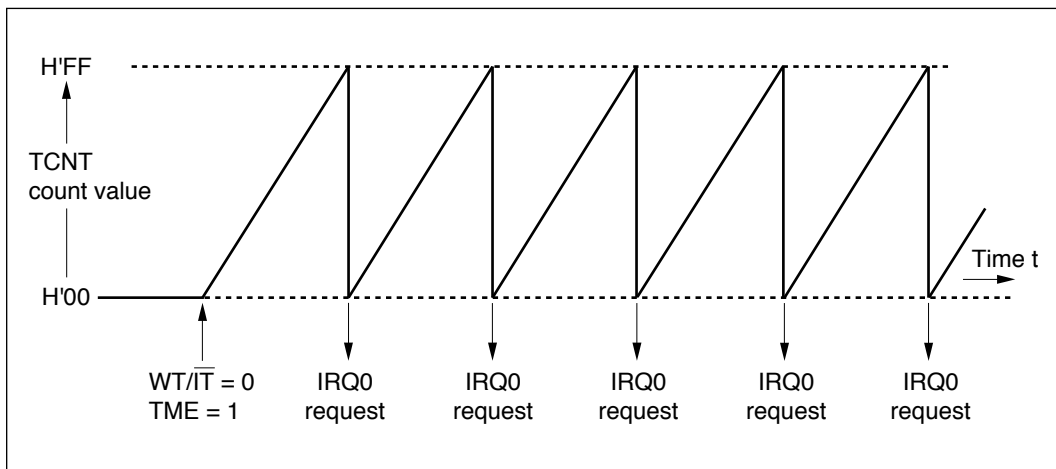

Figure 11-5 Interval Timer Operation

11.3.3 Operation in Software Standby Mode

The watchdog timer has a special function in recovery from software standby mode. WDT settings required when software standby mode is used are described next.

(1) Before Transition to Software Standby Mode: The TME bit in the timer control/status register (TCSR) must be cleared to 0 to stop the watchdog timer counter before execution of the SLEEP instruction. The chip cannot enter software standby mode while the TME bit is set to 1. Before entering software standby mode, software should also set bits CKS2 to CKS0 in TCSR so that the overflow interval is equal to or greater than the settling time of the clock oscillator.

(2) Recovery from Software Standby Mode: In recovery from software standby mode the WDT operates as follows.

When an NMI request signal is received, the clock oscillator starts running and the timer counter (TCNT) starts counting at the rate selected by bits CKS2 to CKS0 in TCSR before software standby mode was entered. When TCNT overflows (changes from H'FF to H'00), the system clock (ϕ) is presumed to be stable and usable, clock signals are supplied to the entire chip, software standby mode ends, and the NMI interrupt-handling routine starts executing. This timer overflow does not set the OVF flag in TCSR to 1, and the TME bit remains cleared to 0.

11.3.4 Timing of Setting of Overflow Flag (OVF)

Figure 11-6 shows the timing of setting of the OVF flag in the timer control/status register (TCSR). The OVF flag is set to 1 when the timer counter overflows. When OVF is set to 1, an IRQ0 interrupt is requested simultaneously.

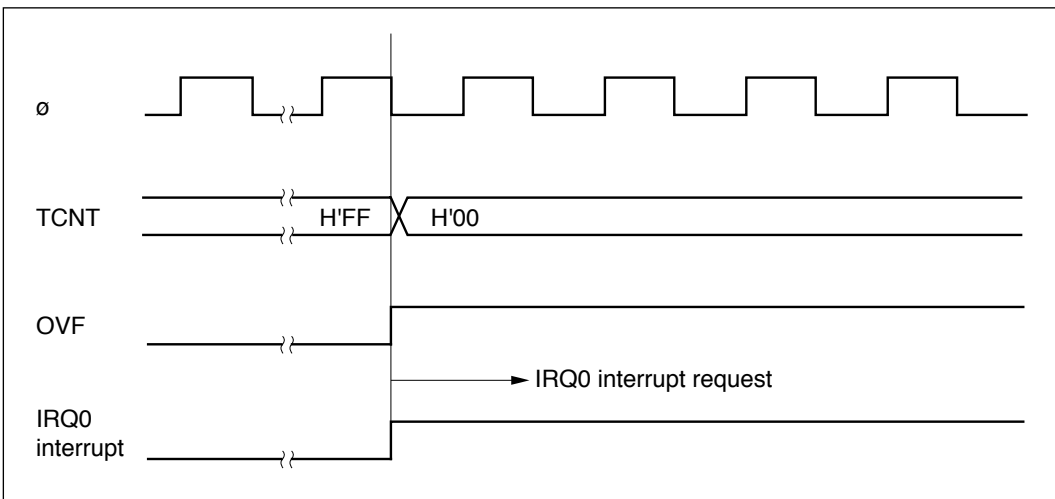

Figure 11-6 Timing of Setting of OVF

11.3.5 Timing of Setting of Watchdog Timer Reset Bit (WRST)

The WRST bit in the reset control/status register (RSTCSR) is valid when $WT/\overline{IT} = 1$ and $TME = 1$. Figure 11-7 shows the timing of setting of WRST and the internal reset timing. The WRST bit is set to 1 when the timer count overflows and OVF is set to 1. At the same time an internal reset signal is generated for the entire H8/538F chip. This internal reset signal clears OVF, but the WRST bit remains set to 1. The reset routine must therefore contain an instruction that clears the WRST bit.

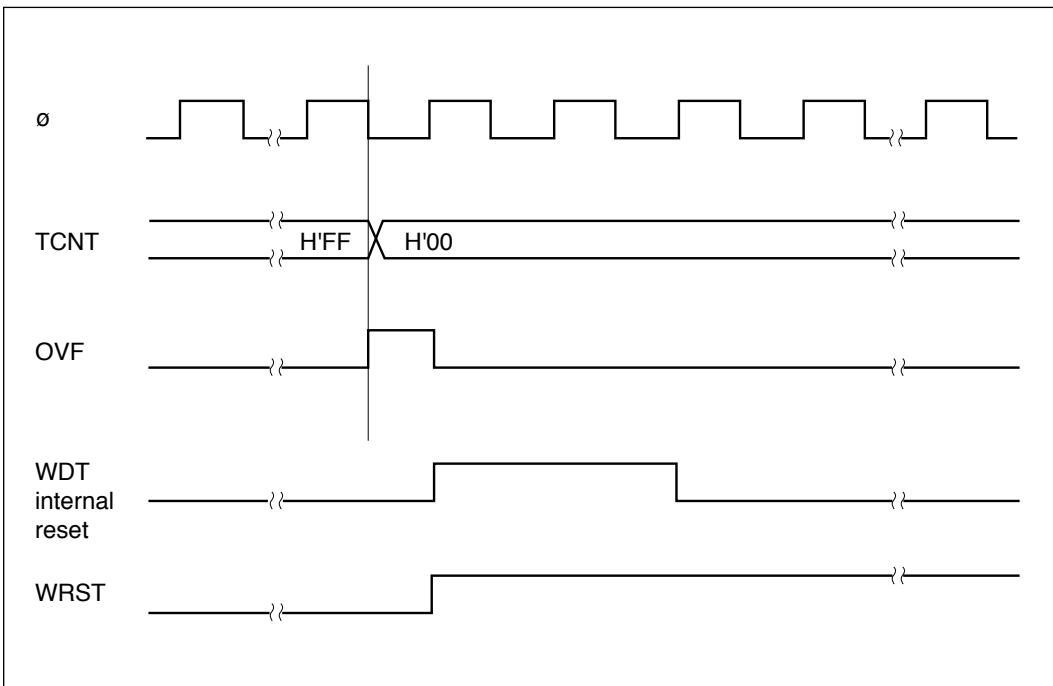

Figure 11-7 Timing of Setting of WRST Bit and Internal Reset

11.4 Usage Notes

(1) Contention between Timer Counter (TCNT) Write and Increment: If a timer counter clock pulse is generated during the T_3 state of a write cycle to the timer counter, the write takes priority and the timer counter is not incremented. See figure 11-8.

Figure 11-8 Contention between TCNT Write and Increment

(2) Changing CKS2 to CKS0 Values: Software should stop the watchdog timer (by clearing the TME bit to 0) before changing the values of bits CKS2 to CKS0 in the timer control/status register (TCSR).

Section 12 Serial Communication Interface

12.1 Overview

The H8/538F has a serial communication interface (SCI) with two independent channels. Both channels are functionally identical. The SCI supports both asynchronous and clocked synchronous serial communication. It also has a multiprocessor communication function for serial communication among two or more processors.

12.1.1 Features

SCI features are listed below.

- Selection of asynchronous or synchronous mode

- a. Asynchronous mode

The SCI can communicate with a UART (universal asynchronous receiver/transmitter), ACIA (asynchronous communication interface adapter), or other chip that employs standard asynchronous serial communication. It can also communicate with two or more other processors using the multiprocessor communication function. There are twelve selectable serial data communication formats.

- Data length: seven or eight bits
- Stop bit length: one or two bits
- Parity: even, odd, or none
- Multiprocessor bit: one or none
- Receive error detection: parity, overrun, and framing errors
- Break detection: by reading the RXD level directly when a framing error occurs

- b. Clocked synchronous mode

Serial data communication is synchronized with a clock signal. The SCI can communicate with other chips having a clocked synchronous communication function.

- Data length: eight bits
- Receive error detection: overrun errors

- Full duplex communication

The transmitting and receiving sections are independent, so the SCI can transmit and receive simultaneously. Both sections use double buffering, so continuous data transfer is possible in both the transmit and receive directions.

- Built-in baud rate generator with selectable bit rates
- Internal or external transmit/receive clock source: baud rate generator or SCK pin
- Four types of interrupts

Transmit-data-empty, transmit-end, receive-data-full, and receive-error interrupts are requested independently. The transmit-data-empty and receive-data-full interrupts can be served by the on-chip data transfer controller (DTC) to transfer data.

12.1.2 Block Diagram

Figure 12-1 shows a block diagram of the SCI.

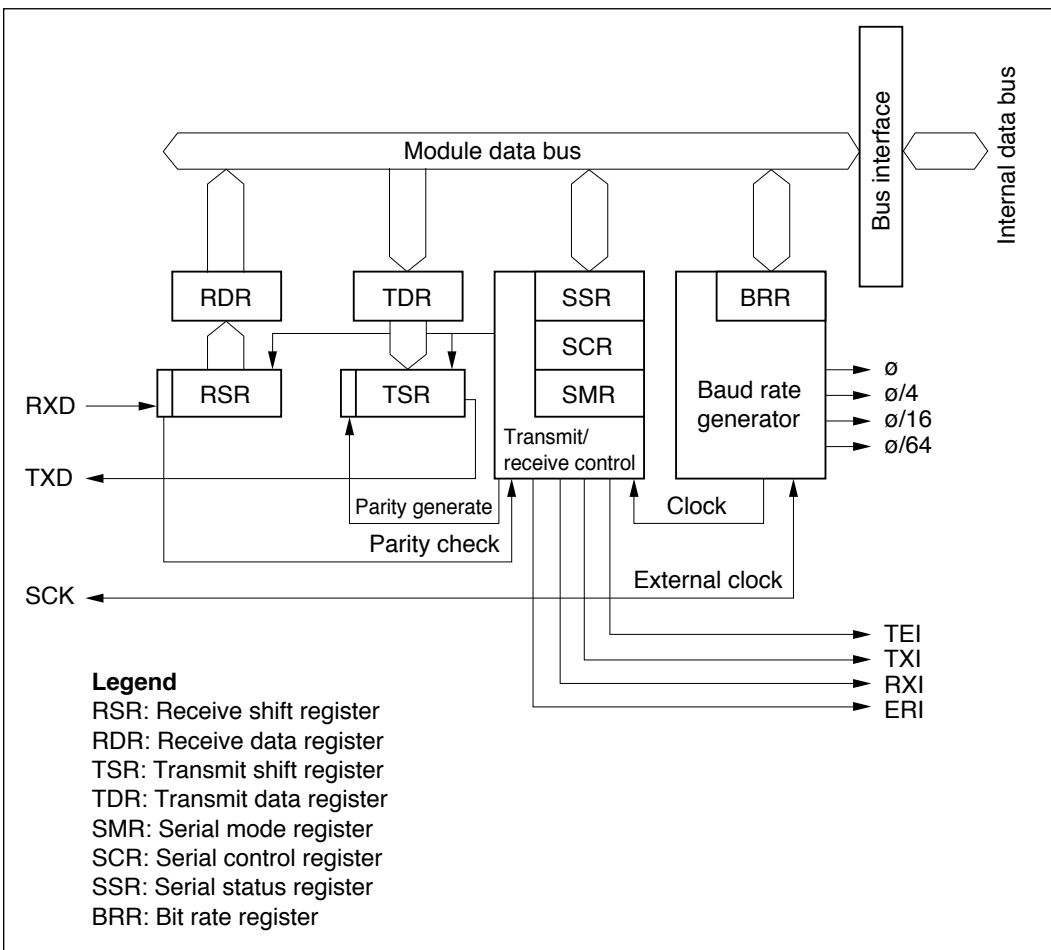

Figure 12-1 SCI Block Diagram

12.1.3 Input/Output Pins

Table 12-1 summarizes the SCI pins.

Table 12-1 SCI Pins

Channel	Pin Name	Abbreviation	Input/Output	Function
1	Serial clock pin	SCK1	Input/output	SCI1 clock input/output
	Receive data pin	RXD1	Input	SCI1 receive data input
	Transmit data pin	TXD1	Output	SCI1 transmit data output
2	Serial clock pin	SCK2	Input/output	SCI2 clock input/output
	Receive data pin	RXD2	Input	SCI2 receive data input
	Transmit data pin	TXD2	Output	SCI2 transmit data output

12.1.4 Register Configuration

Table 12-2 summarizes the SCI registers. These registers select the communication mode (asynchronous or clocked synchronous), specify the data format and bit rate, and control the transmitter and receiver sections.

Table 12-2 Channel 1 Registers

Channel	Address	Name	Abbreviation	R/W	Initial Value
1	H'FEC8	Serial mode register	SMR	R/W	H'00
	H'FEC9	Bit rate register	BRR	R/W	H'FF
	H'FECA	Serial control register	SCR	R/W	H'00
	H'FECEB	Transmit data register	TDR	R/W	H'FF
	H'FECC	Serial status register	SSR	R/(W)*	H'84
	H'FECD	Receive data register	RDR	R	H'00
2	H'FED0	Serial mode register	SMR	R/W	H'00
	H'FED1	Bit rate register	BRR	R/W	H'FF
	H'FED2	Serial control register	SCR	R/W	H'00
	H'FED3	Transmit data register	TDR	R/W	H'FF
	H'FED4	Serial status register	SSR	R/(W)*	H'84
	H'FED5	Receive data register	RDR	R	H'00

Note: * Software can write 0 to clear flags but cannot write 1.

12.2 Register Descriptions

12.2.1 Receive Shift Register

The receive shift register (RSR) receives serial data.

Bit	7	6	5	4	3	2	1	0
R/W	—	—	—	—	—	—	—	—

Data input at the RXD pin are loaded into RSR in the order received, LSB (bit 0) first. In this way the SCI converts received data to parallel form. When one byte has been received, it is automatically transferred to the receive data register (RDR). The H8/500 CPU cannot read or write RSR directly.

12.2.2 Receive Data Register

The receive data register (RDR) stores serial receive data.

Bit	7	6	5	4	3	2	1	0
Initial value	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

The SCI completes the reception of one byte of serial data by moving the received data from the receive shift register (RSR) into RDR for storage. RSR is then ready to receive the next data. This double buffering allows the SCI to receive data continuously.

The H8/500 CPU can read but not write RDR. RDR is initialized to H'00 by a reset and in the standby modes.

12.2.3 Transmit Shift Register

The transmit shift register (TSR) transmits serial data.

Bit	7	6	5	4	3	2	1	0
R/W	—	—	—	—	—	—	—	—

The SCI loads transmit data from the transmit data register (TDR) into TSR, then transmits the data serially from the TXD pin, LSB (bit 0) first. After transmitting one data byte, the SCI automatically loads the next transmit data from TDR into TSR and starts transmitting again. If TDRE is set to 1, however, the SCI does not load the TDR contents into TSR. The H8/500 CPU cannot read or write TSR directly.

12.2.4 Transmit Data Register

The transmit data register (TDR) is an eight-bit register that stores data for serial transmission.

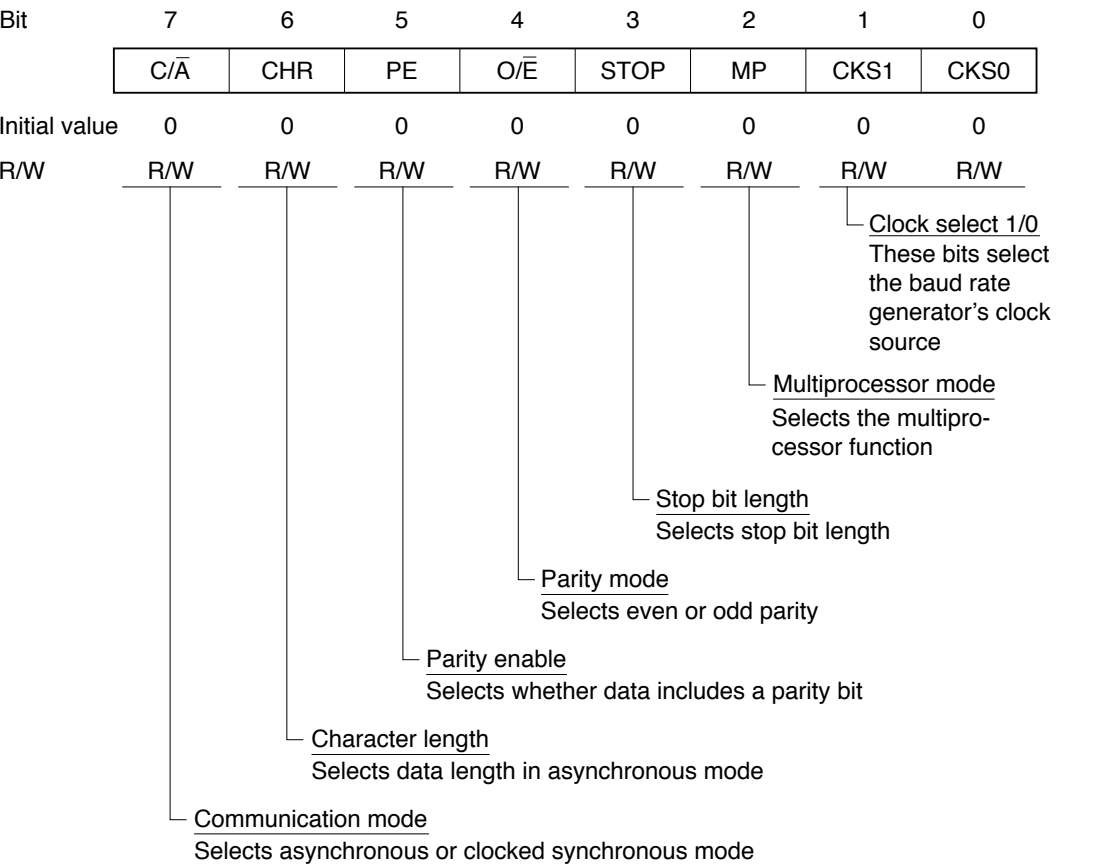

Bit	7	6	5	4	3	2	1	0
Initial value	1	1	1	1	1	1	1	1
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

When the SCI detects that the transmit shift register (TSR) is empty, it moves transmit data written in TDR into TSR and starts serial transmission. Continuous serial transmission is possible by writing the next transmit data in TDR during serial transmission from TSR.

The H8/500 CPU can always read and write TDR. TDR is initialized to H'FF by a reset and in the standby modes.

12.2.5 Serial Mode Register

The serial mode register (SMR) is an eight-bit register that specifies the SCI serial communication format and selects the clock source for the baud rate generator.

The H8/500 CPU can always read and write SMR. SMR is initialized to H'00 by a reset and in the standby modes.

(1) Bit 7—Communication Mode (C/ \bar{A}): Selects whether the SCI operates in asynchronous or clocked synchronous mode.

Bit 7

C/\bar{A}	Description
0	Asynchronous mode (Initial value)
1	Clocked synchronous mode

(2) Bit 6—Character Length (CHR): Selects seven-bit or eight-bit data in asynchronous mode. In clocked synchronous mode the data length is always eight bits, regardless of the CHR setting.

Bit 6

CHR	Description
0	Eight-bit data (Initial value)
1	Seven-bit data*

Note: * When seven-bit data is selected, the MSB of the transmit data register (bit 7) is not transmitted.

(3) Bit 5—Parity Enable (PE): Selects whether to add a parity bit to transmit data and check parity of receive data, in asynchronous mode. In clocked synchronous mode the parity bit is neither added nor checked, regardless of the PE setting.

Bit 5

PE	Description
0	Parity bit not added or checked (Initial value)
1	Parity bit added and checked*

Note: * When PE is set to 1 an even or odd parity bit is added to transmit data, depending on the parity mode (O/E) setting. Receive data parity is checked according to the even/odd (O/E) mode setting.

(4) Bit 4—Parity Mode (O/E): Selects even or odd parity when parity bits are added and checked. The O/E setting is used only in asynchronous mode and only when the parity enable bit (PE) is set to 1 to enable parity generation and checking. The O/E setting is ignored in clocked synchronous mode, or in asynchronous mode when parity is disabled.

Bit 4		
O/E	Description	
0	Even parity*1	(Initial value)
1	Odd parity*2	

Notes: 1. If even parity is selected, the parity bit added to transmit data makes an even number of 1s in the transmitted character and parity bit combined. Receive data must have an even number of 1s in the received character and parity bit combined.

2. If odd parity is selected, the parity bit added to transmit data makes an odd number of 1s in the transmitted character and parity bit combined. Receive data must have an odd number of 1s in the received character and parity bit combined.

(5) Bit 3—Stop Bit Length (STOP): Selects one or two bits as the stop bit length in asynchronous mode. This setting is used only in asynchronous mode. It is ignored in clocked synchronous mode because no stop bits are added.

Bit 3		
STOP	Description	
0	One stop bit*1	(Initial value)
1	Two stop bits*2	

Notes: 1. In transmitting, a single 1 bit is added at the end of each transmitted character.

2. In transmitting, two 1 bits are added at the end of each transmitted character.

In receiving, only the first stop bit is checked, regardless of the STOP bit setting. If the second stop bit is 1 it is treated as a stop bit. If the second stop bit is 0 it is treated as the start bit of the next incoming character.

(6) Bit 2—Multiprocessor Mode (MP): Selects a multiprocessor format. When a multiprocessor format is selected, settings of the parity enable (PE) and parity mode (O/ \bar{E}) bits are ignored. The MP bit setting is used only in asynchronous mode; it is ignored in clocked synchronous mode. For the multiprocessor communication function, see section 12.3.4, “Multiprocessor Communication.”

Bit 2

MP	Description
0	Multiprocessor function disabled (Initial value)
1	Multiprocessor format selected

(7) Bits 1 and 0—Clock Select 1 and 0 (CKS1/0): These bits select the internal clock source of the on-chip baud rate generator. Four clock sources are available: ϕ , $\phi/4$, $\phi/16$, and $\phi/64$. For further information on the clock source, bit rate register settings, and bit rate, see section 12.2.8, “Bit Rate Register.”

Bit 1	Bit 0	Description
CKS1	CKS0	
0	0	System clock (ϕ) (Initial value)
0	1	$\phi/4$
1	0	$\phi/16$
1	1	$\phi/64$

12.2.6 Serial Control Register

The serial control register (SCR) enables the SCI transmitter and receiver, selects serial clock output in asynchronous mode, enables and disables interrupts, and selects the transmit/receive clock.

Bit	7	6	5	4	3	2	1	0
	TIE	RIE	TE	RE	MPIE	TEIE	CKE1	CKE0
Initial value	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
							<u>Clock enable 1/0</u> Selects the SCI clock source	
							<u>Transmit end interrupt enable</u> Enables and disables transmit-end interrupts (TEI)	
							<u>Multiprocessor interrupt enable</u> Enables and disables multiprocessor interrupts	
							<u>Receive enable</u> Enables and disables the receiver	
							<u>Transmit enable</u> Enables and disables the transmitter	
							<u>Receive interrupt enable</u> Enables and disables receive-data-full interrupts (RXI) and receive error interrupts (ERI)	
							<u>Transmit interrupt enable</u> Enables and disables transmit-data-empty interrupts (TXI)	

The H8/500 CPU can always read and write SCR. SCR is initialized to H'00 by a reset and in the standby modes.

(1) Bit 7—Transmit Interrupt Enable (TIE): Enables or disables the transmit-data-empty interrupt (TXI) requested when the transmit data register empty bit (TDRE)* in the serial status register (SSR) is set to 1 due to transfer of serial transmit data from TDR to TSR.

Bit 7

TIE	Description
0	Transmit-data-empty interrupt request (TXI) is disabled* (Initial value)
1	Transmit-data-empty interrupt request (TXI) is enabled

Note: * The TXI interrupt request can be cleared by reading TDRE after it has been set to 1, then clearing TDRE to 0, or by clearing TIE to 0.

(2) Bit 6—Receive Interrupt Enable (RIE): Enables or disables the receive-data-full interrupt (RXI) requested when the receive data register full bit (RDRF) in the serial status register (SSR) is set to 1 due to transfer of serial receive data from RSR to RDR. Also enables or disables receive-error interrupt (ERI) requests.

Bit 6

RIE	Description
0	Receive-data-full interrupt (RXI) and receive-error interrupt (ERI) requests are disabled* (Initial value)
1	Receive-data-full interrupt (RXI) and receive-error interrupt (ERI) requests are enabled

Note: * RXI and ERI interrupt requests can be cleared by reading the RDRF flag or error flag (FER, PER, or ORER) after it has been set to 1, then clearing the flag to 0, or by clearing RIE to 0.

(3) Bit 5—Transmit Enable (TE): Enables or disables the SCI transmitter.

Bit 5

TE	Description
0	Transmitter disabled*1, TXD pin available for general-purpose I/O (Initial value)
1	Transmitter enabled*2, TXD used for transmit data output

Notes: 1. The transmit data register empty bit (TDRE) in the serial status register (SSR) is locked at 1.
2. Serial transmitting starts when the transfer data register empty (TDRE) bit in the serial status register (SSR) is cleared to 0 after writing of transmit data into TDR. Select the transmit format in SMR before setting TE to 1.

(4) Bit 4—Receive Enable (RE): Enables or disables the SCI receiver.

Bit 4

RE	Description
0	Receiver disabled* ¹ , RXD pin available for general-purpose I/O (Initial value)
1	Receiver enabled* ² , RXD used for receive data input

Notes: 1. Clearing RE to 0 does not affect the receive flags (RDRF, FER, PER, ORER). These flags retain their previous values.
2. Serial receiving starts when a start bit is detected in asynchronous mode, or serial clock input is detected in clocked synchronous mode. Select the receive format in SMR before setting RE to 1.

(5) Bit 3—Multiprocessor Interrupt Enable (MPIE): Enables or disables multiprocessor interrupts. The MPIE setting is used only in asynchronous mode, and only if the multiprocessor mode bit (MP) in the serial mode register (SMR) is set to 1. The MPIE setting is ignored in clocked synchronous mode or when the MP bit is cleared to 0.

Bit 3

MPIE	Description
0	Multiprocessor interrupts are disabled (normal receive operation) (Initial value)
1	Multiprocessor interrupts are enabled.* Receive-data-full interrupt requests (RXI), receive-error interrupt requests (ERI), and setting of the RDRF, FER, and ORER status flags in the serial status register (SSR) are disabled. MPIE is cleared to 0 when: 1. MPIE is cleared to 0, or 2. Multiprocessor bit (MPB) is set to 1 in receive data.

Note: * The SCI does not transfer receive data from RSR to RDR, does not detect receive errors, and does not set the RDRF, FER, and ORER flags in the serial status register (SSR). When it receives data with the multiprocessor bit (MPB) set to 1, the SCI automatically clears MPIE to 0, enables RXI and ERI interrupts (if the RIE bit in SCR is set to 1), and allows FER and ORER to be set.

(6) Bit 2—Transmit-End Interrupt Enable (TEIE): Enables or disables the transmit-end interrupt (TEI) requested if TDR does not contain new transmit data when the MSB is transmitted.

Bit 2

TEIE	Description
0	Transmit-end interrupt (TEI) requests are disabled* (Initial value)
1	Transmit-end interrupt (TEI) requests are enabled*

Note: * The TEI request can be cleared by reading the TDRE bit in the serial status register (SSR) after it has been set to 1, then clearing TDRE to 0, thereby clearing the transmit end (TEND) bit to 0; or by clearing the TEIE bit to 0.

(7) Bits 1 and 0—Clock Enable 1 and 0 (CKE1/0): These bits select the SCI clock source and enable or disable clock output from the SCK pin. Depending on the combination of CKE1 and CKE0, the SCK pin can be used for general-purpose input/output, serial clock output, or serial clock input.

The CKE0 setting is valid only in asynchronous mode, and only when the SCI is internally clocked (CKE1 = 0). The CKE0 setting is ignored in clocked synchronous mode, or when an external clock source is selected (CKE1 = 1). Select the SCI operating mode in the serial mode register (SMR) before setting CKE1 and CKE0. For further details on selection of the SCI clock source, see table 12-6 in section 12.3, “Operation.”

Bit 1 Bit 0

CKE1	CKE0	Description
0	0	Asynchronous mode Internal clock, SCK pin available for general-purpose input/output* ¹
		Clocked synchronous mode Internal clock, SCK pin used for serial clock output* ¹
0	1	Asynchronous mode Internal clock, SCK pin used for clock output* ²
		Clocked synchronous mode Internal clock, SCK pin used for serial clock output
1	0	Asynchronous mode External clock, SCK pin used for clock input* ³
		Clocked synchronous mode External clock, SCK pin used for serial clock input
1	1	Asynchronous mode External clock, SCK pin used for clock input* ³
		Clocked synchronous mode External clock, SCK pin used for serial clock input

Notes: 1. Initial value

2. The output clock frequency is the same as the bit rate.

3. The input clock frequency is 16 times the bit rate.

12.2.7 Serial Status Register

The serial status register (SSR) is an eight-bit register containing multiprocessor bit values, and status flags that indicate SCI operating status.

Bit	7	6	5	4	3	2	1	0
	TDRE	RDRF	ORER	FER	PER	TEND	MPB	MPBT
Initial value	1	0	0	0	0	1	0	0
R/W	R/(W)*	R/(W)*	R/(W)*	R/(W)*	R/(W)*	R	R	R/W
								<div>Multiprocessor bit transfer Value of multiprocessor bit to be transmitted</div>
								<div>Multiprocessor bit Stores received multiprocessor bit value</div>
								<div>Transmit end Status flag indicating end of transmission</div>
								<div>Parity error Status flag indicating detection of a receive parity error</div>
								<div>Framing error Status flag indicating detection of a receive framing error</div>
								<div>Overrun error Status flag indicating detection of a receive overrun error</div>
								<div>Receive data register full Status flag indicating that the SCI has stored receive data in RDR</div>
								<div>Transmit data register empty Status flag indicating that the SCI has loaded transmit data from TDR into TSR and new data can be written in TDR</div>

Note: * Software can write 0 to clear the flag, but cannot write 1.

The H8/500 CPU can always read and write SSR, but cannot write 1 in the status flags (TDRE, RDRF, ORER, PER, and FER). These flags can be cleared to 0 only if they have first been read after being set to 1. Bits 2 (TEND) and 1 (MPB) are read-only bits that cannot be written.

SSR is initialized to H'84 by a reset and in the standby modes.

(1) Bit 7—Transmit Data Register Empty (TDRE): Indicates that the SCI has loaded transmit data from TDR into TSR and new data can be written in TDR.

Bit 7

TDRE	Description
0	TDR contains valid transmit data TDRE is cleared to 0 when: 1. Software reads TDRE after it has been set to 1, then writes 0 in TDRE 2. The DTC writes data in TDR
1	TDR does not contain valid transmit data (Initial value) TDRE is set to 1 when: 1. The chip is reset or enters standby mode 2. The TE bit in the serial control register (SCR) is cleared to 0, or 3. TDR contents are loaded into TSR, so new data can be written in TDR

(2) Bit 6—Receive Data Register Full (RDRF): Indicates that RDR contains new receive data.

Bit 6

RDRF	Description
0	RDR does not contain new receive data (Initial value) RDRF is cleared to 0 when: 1. The chip is reset or enters standby mode 2. Software reads RDRF after it has been set to 1, then writes 0 in RDRF 3. The DTC reads data from RDR
1	RDR contains new receive data RDRF is set to 1 when serial data are received normally and transferred from RSR to RDR.

Note: RDR and RDRF are not affected by detection of receive errors or by clearing of the RE bit to 0 in the serial control register. They retain their previous contents. If RDRF is still set to 1 when reception of the next data ends, an overrun error (ORER) occurs and receive data are lost.

(3) Bit 5—Overrun Error (ORER): Indicates that data reception ended abnormally due to an overrun error.

Bit 5

ORER	Description
0	Receiving is in progress or has ended normally (Initial value)* ¹ ORER is cleared to 0 when: 1. The chip is reset or enters standby mode 2. Software reads ORER after it has been set to 1, then writes 0 in ORER
1	A receive overrun error occurred* ² ORER is set to 1 if reception of the next serial data ends when RDRF is set to 1

Notes: 1. Clearing the RE bit to 0 in the serial control register does not affect the ORER bit, which retains its previous value.
2. RDR continues to hold the receive data before the overrun error, so subsequent receive data are lost. Serial receiving cannot continue while ORER is set to 1. In clocked synchronous mode, serial transmitting is also disabled.

(4) Bit 4—Framing Error (FER): Indicates that data reception ended abnormally due to a framing error in asynchronous mode.

Bit 4

FER	Description
0	Receiving is in progress or has ended normally (Initial value)* ¹ FER is cleared to 0 when: 1. The chip is reset or enters standby mode 2. Software reads FER after it has been set to 1, then writes 0 in FER
1	A receive framing error occurred* ² FER is set to 1 if the stop bit at the end of receive data is checked and found to be 0.

Notes: 1. Clearing the RE bit to 0 in the serial control register does not affect the FER bit, which retains its previous value.
2. When the stop bit length is two bits, only the first bit is checked. The second stop bit is not checked. When a framing error occurs the SCI transfers the receive data into RDR but does not set RDRF. Serial receiving cannot continue while FER is set to 1. In clocked synchronous mode, serial transmitting is also disabled.

(5) Bit 3—Parity Error (PER): Indicates that data reception ended abnormally due to a parity error in asynchronous mode.

Bit 3

PER	Description
0	Receiving is in progress or has ended normally (Initial value)*1 PER is cleared to 0 when: 1. The chip is reset or enters standby mode 2. Software reads PER after it has been set to 1, then writes 0 in PER
1	A receive parity error occurred*2 PER is set to 1 if the number of 1s in receive data, including the parity bit, does not match the even or odd parity setting of the parity mode bit (O/Ē) in the serial mode register (SMR).

Notes: 1. Clearing the RE bit to 0 in the serial control register does not affect the PER bit, which retains its previous value.
2. When a parity error occurs the SCI transfers the receive data into RDR but does not set RDRF. Serial receiving cannot continue while PER is set to 1. In clocked synchronous mode, serial transmitting is also disabled.

(6) Bit 2—Transmit End (TEND): Indicates that when the last bit of a serial character was transmitted TDR did not contain new transmit data, so transmission has ended. TEND is a read-only bit and cannot be written.

Bit 2

TEND	Description
0	Transmission is in progress TEND is cleared to 0 when: 1. Software reads TDRE after it has been set to 1, then writes 0 in TDRE 2. The DTC writes data in TDR
1	End of transmission (Initial value) TEND is set to 1 when: 1. The chip is reset or enters standby mode 2. TE is cleared to 0 in the serial control register (SCR) 3. TDRE is 1 when the last bit of a serial character (1 byte) is transmitted

(7) Bit 1—Multiprocessor Bit (MPB): Stores the value of the multiprocessor bit in receive data when a multiprocessor format is used in asynchronous mode. MPB is a read-only bit and cannot be written.

Bit 1

MPB	Description
0	Multiprocessor bit value in receive data is 0* (Initial value)
1	Multiprocessor bit value in receive data is 1

Note: * If RE is cleared to 0 when a multiprocessor format is selected, MPB retains its previous value.

(8) Bit 0—Multiprocessor Bit Transfer (MPBT): Stores the value of the multiprocessor bit added to transmit data when a multiprocessor format is selected for transmitting in asynchronous mode. The MPBT setting is ignored in clocked synchronous mode, when a multiprocessor format is not selected, or when the SCI is not transmitting.

Bit 0

MPBT	Description
0	Multiprocessor bit value in transmit data is 0 (Initial value)
1	Multiprocessor bit value in transmit data is 1

12.2.8 Bit Rate Register

The bit rate register (BRR) is an eight-bit register that, together with the CKS1 and CKS0 bits in the serial mode register (SMR) that select the baud rate generator clock source, determines the serial transmit/receive bit rate.

Bit	7	6	5	4	3	2	1	0
Initial value	1	1	1	1	1	1	1	1
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

The H8/500 CPU can always read and write BRR. BRR is initialized to H'FF by a reset and in the standby modes. SCI1 and SCI2 have independent baud rate generator control, so different values can be set in the two channels.

Table 12.3 shows examples of BRR settings in asynchronous mode.

Table 12-3 Examples of Bit Rates and BRR Settings in Asynchronous Mode (1)

Bit Rate (Bits/s)	ϕ (MHz)											
	1			1.2288			2			2.097152		
	n	N	Error (%)	n	N	Error (%)	n	N	Error (%)	n	N	Error (%)

5 M											—	—

Note: Settings with an error of 1% or less are recommended.

Legend

Blank: No setting available

—: Setting possible, but error occurs

*: Continuous transmit/receive not possible

The BRR setting is calculated as follows.

Asynchronous mode:

$$N = \frac{\phi}{64 \times 2^{2n-1} \times B} \times 10^6 - 1$$

Synchronous mode:

$$N = \frac{\phi}{8 \times 2^{2n-1} \times B} \times 10^6 - 1$$

B: bit rate

N: BRR setting for baud rate generator ($0 \leq N \leq 255$)

ϕ : Operating frequency (MHz)

n: baud rate generator clock source (n = 0, 1, 2, 3)
 (For the clock sources and values of n, see the table below.)

n	Clock Source	SMR Settings	
		CKS1	CKS0
0	ø	0	0
1	ø/4	0	1
2	ø/16	1	0
3	ø/64	1	1

The bit rate error in asynchronous mode is calculated as follows.

$$\text{Error (\%)} = \left\{ \frac{\varnothing \times 10^6}{(N + 1) \times B \times 64 \times 2^{2n-1}} - 1 \right\} \times 100$$

Table 12-5 indicates the maximum bit rates in asynchronous mode for various system clock frequencies. Tables 12-6 and 12-7 indicate the maximum bit rates for external clock input.

12.3 Operation

12.3.1 Overview

The SCI has an asynchronous mode in which characters are synchronized individually, and a clocked synchronous mode in which communication is synchronized with clock pulses. Serial communication is possible in either mode. Asynchronous or clocked synchronous mode and the communication format are selected in the serial mode register (SMR), as shown in table 12-8. The SCI clock source is selected by the C/\bar{A} bit in the serial mode register (SMR) and the CKE1 and CKE0 bits in the serial control register (SCR), as shown in table 12-9.

(1) Asynchronous Mode

- Data length is selectable: seven or eight bits.
- Parity and multiprocessor bits are selectable. So is the stop bit length (one or two bits). The foregoing selections constitute the communication format.
- In receiving, it is possible to detect framing errors (FER), parity errors (PER), overrun errors (ORER), and the break state.
- An internal or external clock can be selected as the SCI clock source.
 - When an internal clock is selected, the SCI operates using the on-chip baud rate generator, and can output a serial clock signal with a frequency matching the bit rate.
 - When an external clock is selected, the external clock input must have a frequency 16 times the bit rate. (The on-chip baud rate generator is not used.)

(2) Clocked Synchronous Mode

- The communication format has a fixed eight-bit data length.
- In receiving, it is possible to detect overrun errors (ORER).
- An internal or external clock can be selected as the SCI clock source.
 - When an internal clock is selected, the SCI operates using the on-chip baud rate generator, and outputs a serial clock signal to external devices.
 - When an external clock is selected, the SCI operates on the input serial clock. The on-chip baud rate generator is not used.

Table 12-8 Serial Mode Register Settings and SCI Communication Formats

SMR Settings					SCI Communication Format				
Bit 7	Bit 6	Bit 5	Bit 2	Bit 3	Mode	Data Length	Parity Bit	Multi-processor Bit	Stop Bit Length
C/A	CHR	PE	MP	STOP					
0	0	0	0	0	Asynchronous mode	8-bit data	Absent	Absent	1 bit
				1					2 bits
		1		0					1 bit
				1					2 bits
	1	0		0		7-bit data	Absent		1 bit
				1					2 bits
		1		0					1 bit
				1					2 bits
	0	*	1	0	Asynchronous mode (multiprocessor format)	8-bit data	Absent	Present	1 bit
		*		1					2 bits
	1	*		0		7-bit data			1 bit
		*		1					2 bits
1	*	*	*	*	Clocked synchronous mode	8-bit data		Absent	None

Note: Asterisks (*) in the table indicate don't-care bits.

Table 12-9 SMR and SCR Settings and SCI Clock Source Selection

SMR	SCR Settings		SCI Transmit/Receive Clock		
Bit 7	Bit 1	Bit 0	Mode	Clock Source	SCK Pin Function
C/A	CKE1	CKE0			
0	0	0	Asynchronous mode	Internal	General-purpose input/output (SCI does not use the SCK pin)
		1			Outputs a clock with frequency matching the bit rate
	1	0		External	Inputs a clock with frequency 16 times the bit rate
		1			
1	0	0	Clocked synchronous mode	Internal	Outputs the serial clock
		1			
	1	0		External	Inputs the serial clock
		1			

12.3.2 Operation in Asynchronous Mode

In asynchronous mode each transmitted or received character begins with a start bit and ends with a stop bit. Serial communication is synchronized one character at a time.

The transmitting and receiving sections of the SCI are independent, so full duplex communication is possible. The transmitter and receiver are both double buffered, so data can be written and read while transmitting and receiving are in progress, enabling continuous transmitting and receiving.

Figure 12-2 shows the general format of asynchronous serial communication. In asynchronous serial communication the communication line is normally held in the mark (high) state. The SCI monitors the line and starts serial communication when the line goes to the space (low) state, indicating a start bit. One serial character consists of a start bit (low), data (LSB first), parity bit (high or low), and stop bit (high), in that order.

When receiving in asynchronous mode, the SCI synchronizes on the falling edge of the start bit. The SCI samples each data bit on the eighth pulse of a clock with a frequency 16 times the bit rate. Receive data are latched at the center of each bit.

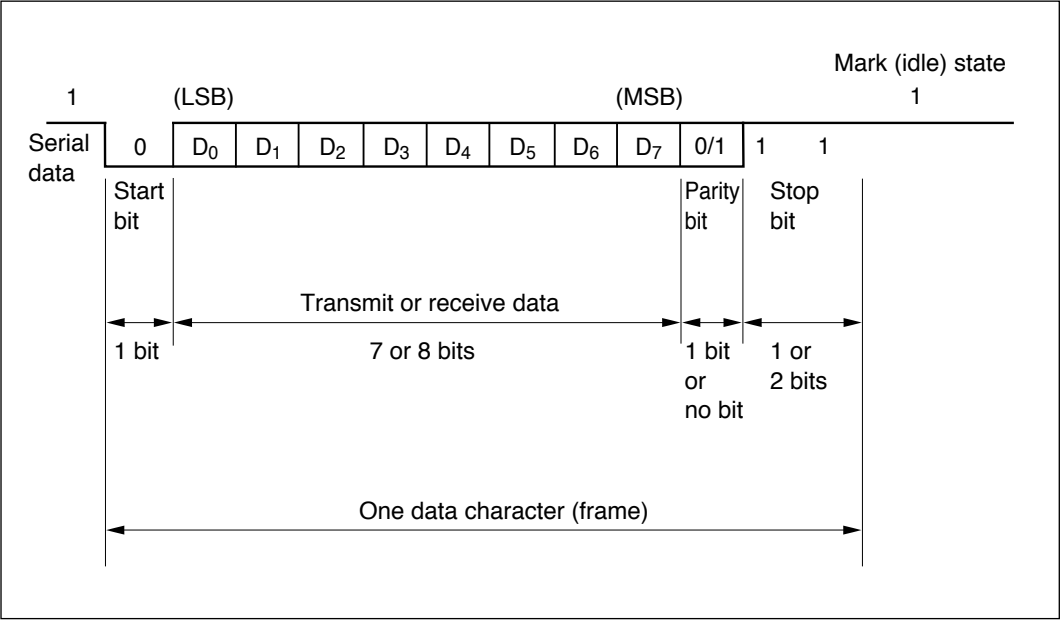

Figure 12-2 Data Format in Asynchronous Communication
(Example: 8-Bit Data with Parity and Two Stop Bits)

(1) Transmit/Receive Formats: Table 12-10 shows the 12 communication formats that can be selected in asynchronous mode. The format is selected by settings in the serial mode register (SMR).

Table 12-10 Serial Communication Formats (Asynchronous Mode)

SMR Settings				Serial Communication Format and Frame Length											
CHR	PE	MP	STOP	1	2	3	4	5	6	7	8	9	10	11	12
0	0	0	0	S				8-bit data					STOP		
0	0	0	1	S				8-bit data					STOP	STOP	
0	1	0	0	S				8-bit data					P	STOP	
0	1	0	1	S				8-bit data					P	STOP	STOP
1	0	0	0	S				7-bit data					STOP		
1	0	0	1	S				7-bit data					STOP	STOP	
1	1	0	0	S				7-bit data					P	STOP	
1	1	0	1	S				7-bit data					P	STOP	STOP
0	*	1	0	S				8-bit data					MPB	STOP	
0	*	1	1	S				8-bit data					MPB	STOP	STOP
1	*	1	0	S				7-bit data					MPB	STOP	
1	*	1	1	S				7-bit data					MPB	STOP	STOP

SMR: serial mode register

P: parity bit

S: start bit

MPB: multiprocessor bit

STOP: stop bit

Note: Asterisks (*) in the table indicate don't-care bits.

(2) Clock: An internal clock generated by the on-chip baud rate generator or an external clock input from the SCK pin can be selected as the SCI transmit/receive clock. The clock source is selected by the C/\overline{A} bit in the serial mode register (SMR) and bits CKE1 and CKE0 in the serial control register (SCR). See table 12-9.

When an external clock is input at the SCK pin, it must have a frequency equal to 16 times the desired bit rate.

When the SCI operates on an internal clock, it can output a clock signal at the SCK pin. The frequency of this output clock is equal to the bit rate. The phase is aligned as in figure 12-3 so that the rising edge of the clock occurs at the center of each transmit data bit.

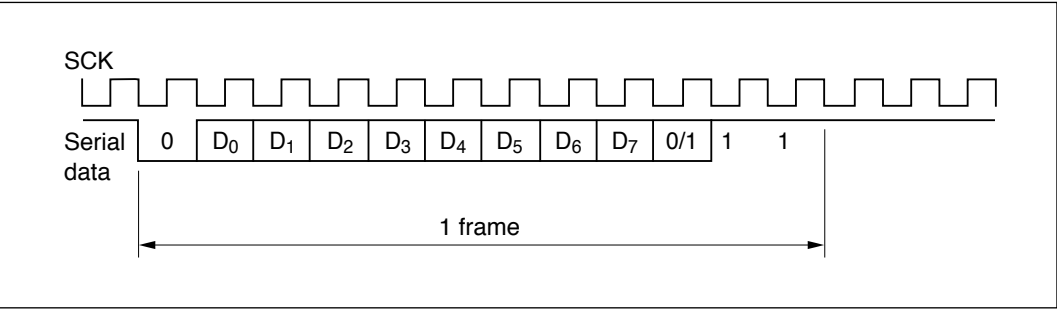

Figure 12-3 Phase Relationship between Output Clock and Serial Data (Asynchronous Mode)

(3) Transmitting and Receiving Data

SCI Initialization (asynchronous mode): Before transmitting or receiving, software must clear the TE and RE bits to 0 in the serial control register (SCR), then initialize the SCI as follows.

When changing the communication mode or format, always clear the TE and RE bits to 0 before following the procedure given below. Clearing TE to 0 sets TDRE to 1 and initializes the transmit shift register (TSR). Clearing RE to 0, however, does not initialize the RDRF, PER, FER, and ORER flags and receive data register (RDR), which retain their previous contents.

When an external clock is used, the clock should not be stopped during initialization or subsequent operation. SCI operation becomes unreliable if the clock is stopped.

Figure 12-4 is a sample flowchart for initializing the SCI.

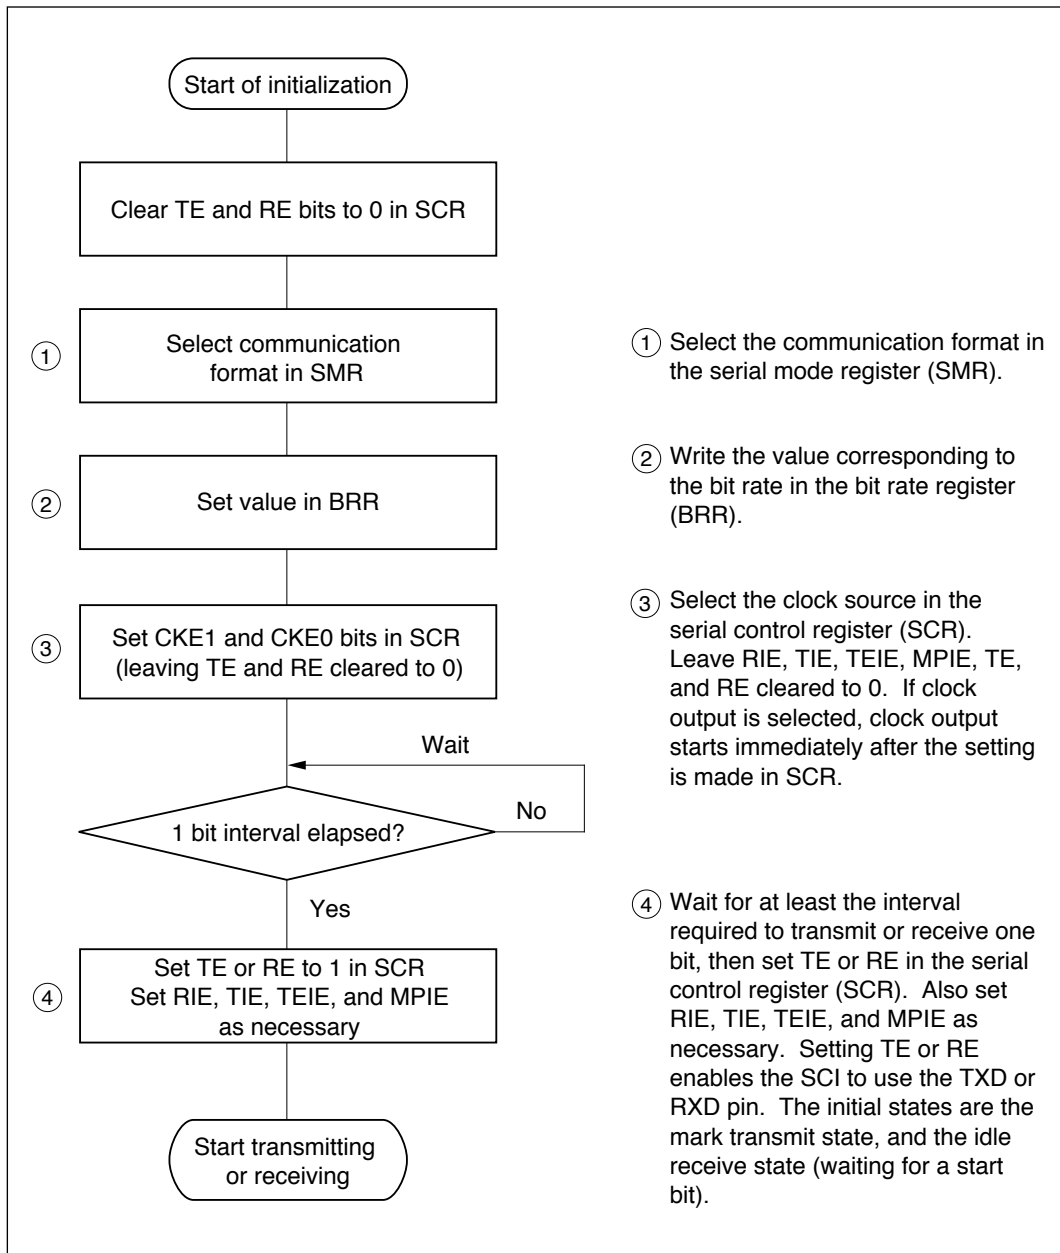

Figure 12-4 Sample Flowchart for SCI Initialization

Transmitting Serial Data (Asynchronous Mode): Figure 12-5 shows a sample flowchart for transmitting serial data and indicates the procedure to follow.

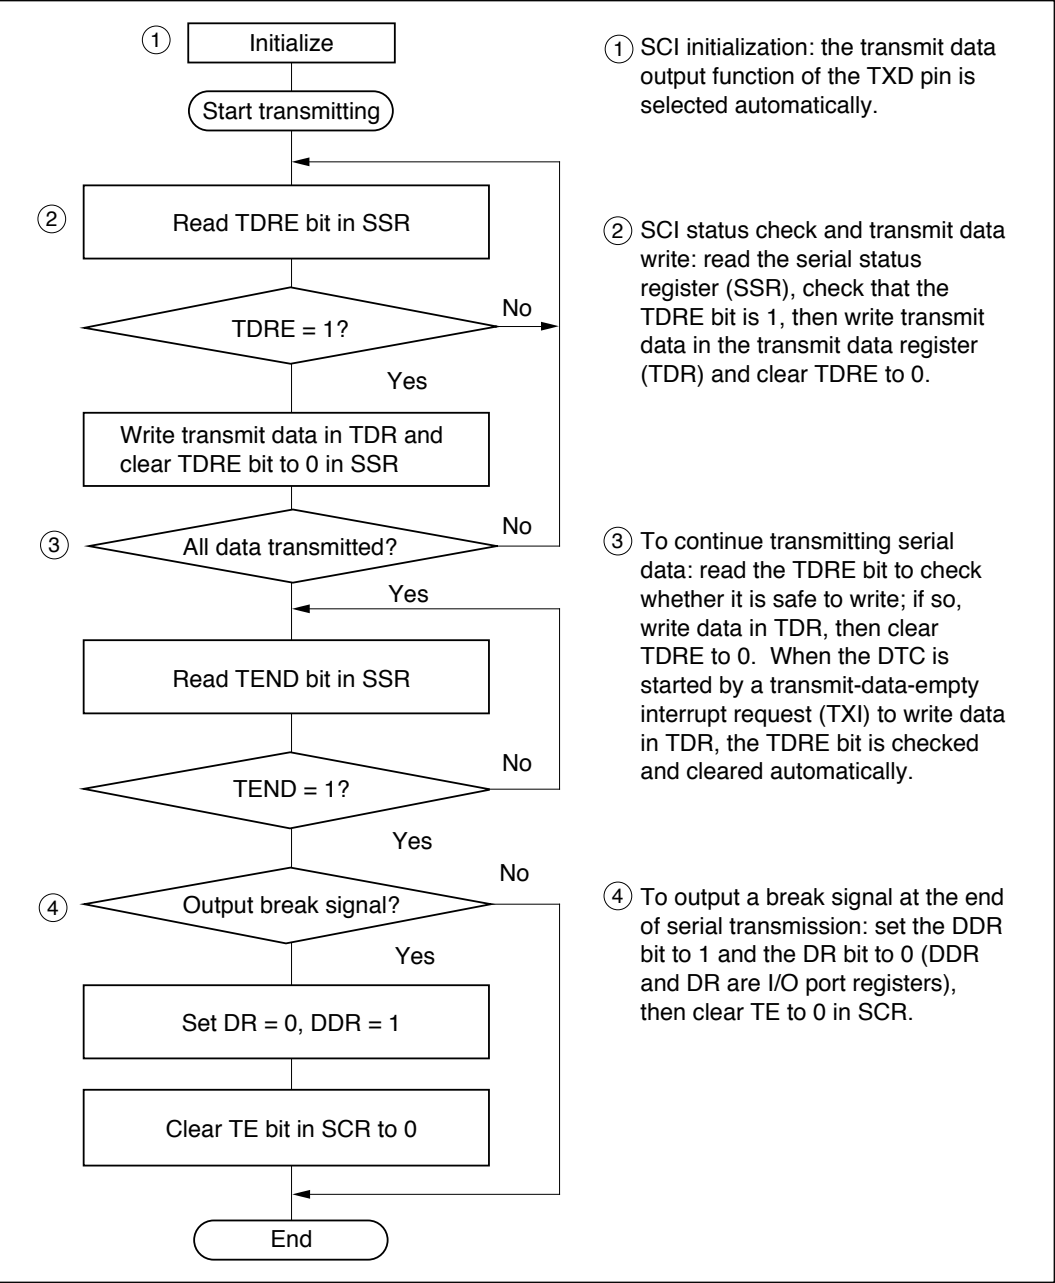

Figure 12-5 Sample Flowchart for Transmitting Serial Data

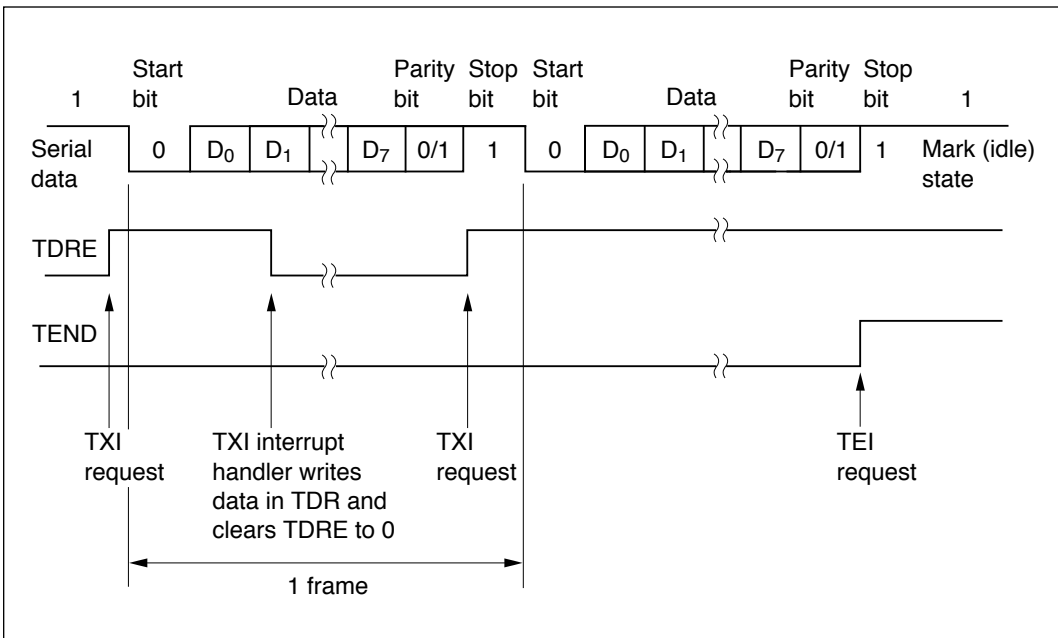

In transmitting serial data, the SCI operates as follows.

1. The SCI monitors the TDRE bit in SSR. When TDRE is cleared to 0 the SCI recognizes that the transmit data register (TDR) contains new data, and loads this data from TDR into the transmit shift register (TSR).
2. After loading the data from TDR into TSR, the SCI sets the TDRE bit to 1 and starts transmitting. If the transmit-data-empty interrupt enable bit (TIE) is set to 1 in SCR, the SCI requests a transmit-data-empty interrupt (TXI) at this time.

Serial transmit data are transmitted in the following order from the TXD pin:

- a. Start bit: one 0 bit is output.
 - b. Transmit data: seven or eight bits are output, LSB first.
 - c. Parity bit or multiprocessor bit: one parity bit (even or odd parity) or one multiprocessor bit is output. Formats in which neither a parity bit nor a multiprocessor bit is output can also be selected.
 - d. Stop bit: one or two 1 bits (stop bits) are output.
 - e. Mark state: output of 1 bits continues until the start bit of the next transmit data.
3. The SCI checks the TDRE bit when it outputs the stop bit. If TDRE is 0, the SCI loads new data from TDR into TSR, outputs the stop bit, then begins serial transmission of the next frame. If TDRE is 1, the SCI sets the TEND bit to 1 in SSR, outputs the stop bit, then continues output of 1 bits in the mark state. If the transmit-end interrupt enable bit (TEIE) in SCR is set to 1, a transmit-end interrupt (TEI) is requested.

Figure 12-6 shows an example of SCI transmit operation in asynchronous mode.

**Figure 12-6 Example of SCI Transmit Operation
(8-Bit Data with Parity and One Stop Bit)**

Receiving Serial Data (Asynchronous Mode): Figure 12-7 shows a sample flowchart for receiving serial data and indicates the procedure to follow.

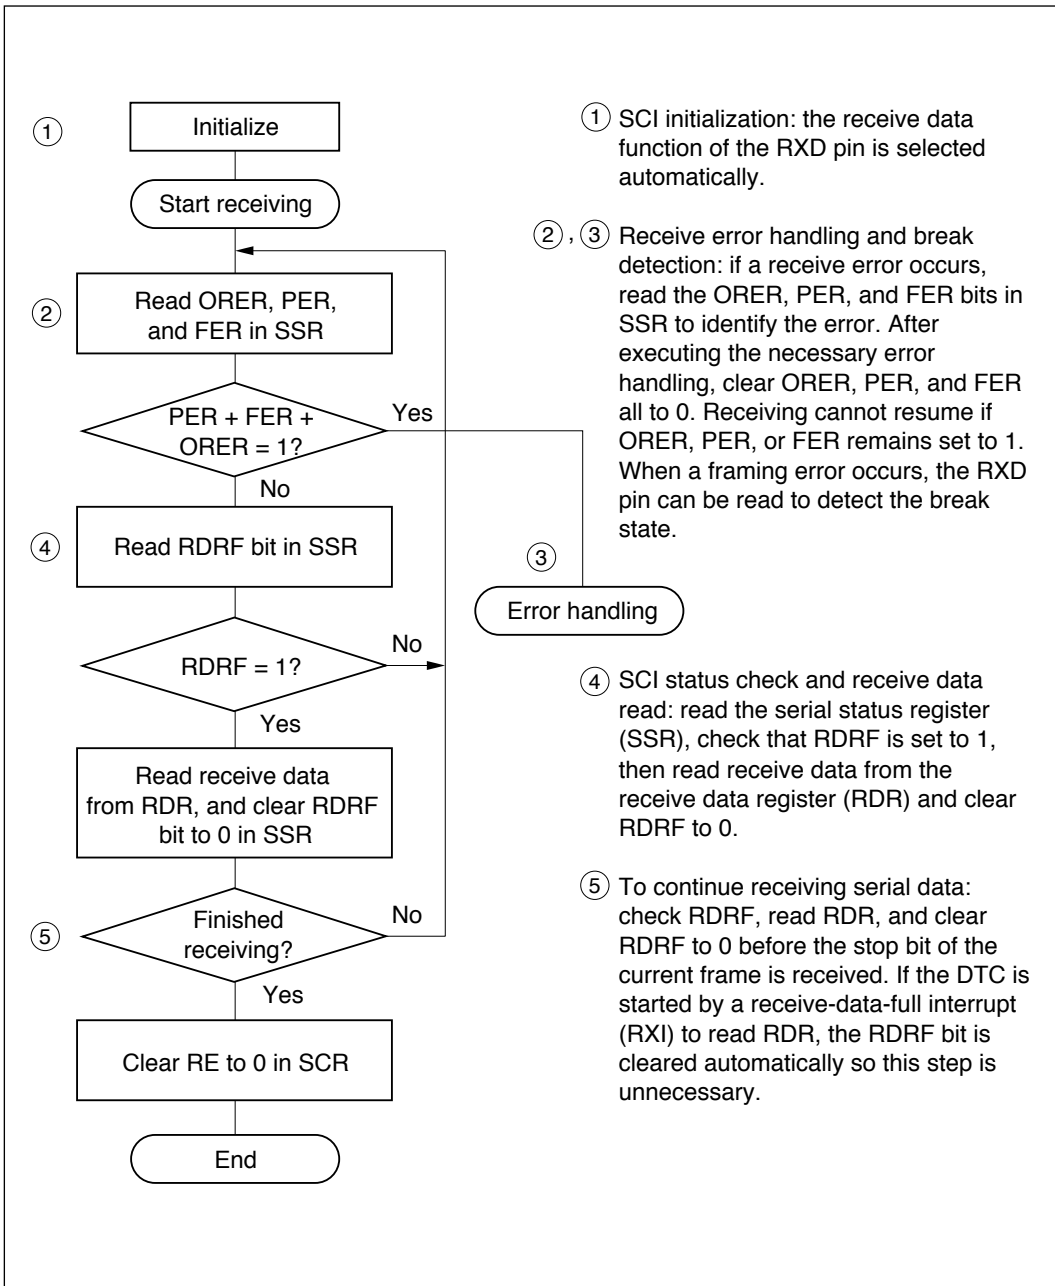

Figure 12-7 Sample Flowchart for Receiving Serial Data

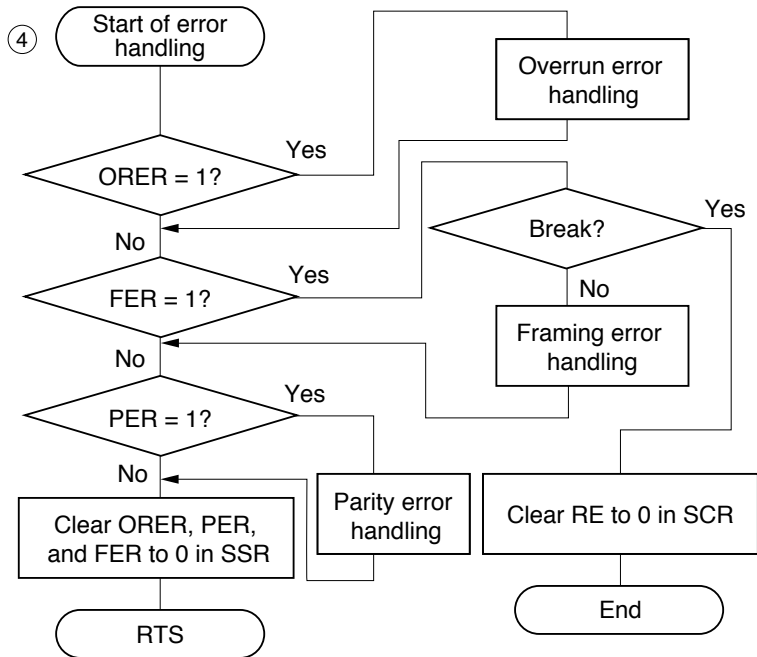

Figure 12-7 Sample Flowchart for Receiving Serial Data (cont)

In receiving, the SCI operates as follows.

1. The SCI monitors the receive data line. When it detects a start bit, the SCI synchronizes internally and starts receiving.
2. Receive data are shifted into RSR in order from LSB to MSB.
3. The parity bit and stop bit are received.

After receiving these bits, the SCI makes the following checks:

- a. Parity check: the number of 1s in the receive data must match the even or odd parity setting of the O/E bit in SMR.
- b. Stop bit check: the stop bit value must be 1. If there are two stop bits, only the first stop bit is checked.
- c. Status check: RDRF must be 0 so that receive data can be loaded from RSR into RDR.

If these checks all pass, the SCI sets RDRF to 1 and stores the received data in RDR. If one of the checks fails (receive error), the SCI operates as indicated in table 12-11.

Note: When a receive error flag is set, further receiving is disabled. When receiving resumes after an error flag was set, the RDRF bit is not set to 1.

4. After setting RDRF to 1, if the receive-data-full interrupt enable bit (RIE) is set to 1 in SCR, the SCI requests a receive-data-full interrupt (RXI). If one of the error flags (ORER, PER, or FER) is set to 1 and the receive-data-full interrupt enable bit (RIE) in SCR is also set to 1, the SCI requests a receive-error interrupt (ERI).

Figure 12-8 shows an example of SCI receive operation in asynchronous mode.

Table 12-11 Receive Error Conditions and SCI Operation

Receive Error	Abbreviation	Condition	Data Transfer
Overrun error	ORER	Receiving of next data ends while RDRF is still set to 1 in SSR	Receive data not loaded from RSR into RDR
Framing error	FER	Stop bit is 0	Receive data loaded from RSR into RDR
Parity error	PER	Parity of receive data differs from even/odd parity setting in SMR	Receive data loaded from RSR into RDR

**Figure 12-8 Example of SCI Receive Operation
(8-Bit Data with Parity and One Stop Bit)**

12.3.3 Clocked Synchronous Operation

In clocked synchronous mode, the SCI transmits and receives data in synchronization with clock pulses. This mode is suitable for high-speed serial communication.

The SCI transmitter and receiver share the same clock but are otherwise independent, so full duplex communication is possible. The transmitter and receiver are also double buffered, so continuous transmitting or receiving is possible by reading or writing data while transmitting or receiving is in progress.

Figure 12-9 shows the general format in clocked synchronous serial communication.

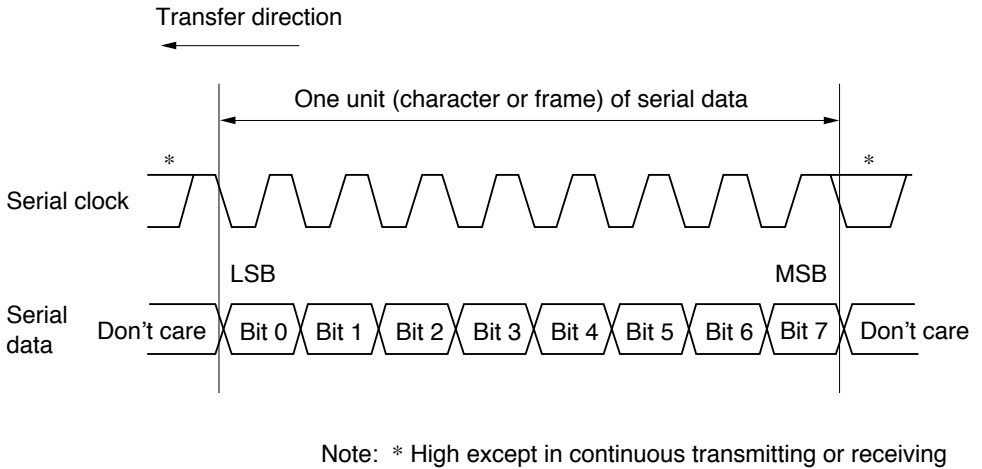

Figure 12-9 Data Format in Clocked Synchronous Communication

In clocked synchronous serial communication, each data bit is placed on the communication line from one falling edge of the serial clock to the next. Data are guaranteed valid at the rising edge of the serial clock. In each character, the serial data bits are transmitted in order from LSB (first) to MSB (last). After output of the MSB, the communication line remains in the state of the MSB. In clocked synchronous mode the SCI receives data by synchronizing with the rising edge of the serial clock.

(1) Communication Format: The data length is fixed at eight bits. No parity bit or multiprocessor bit can be added.

(2) Clock: An internal clock generated by the on-chip baud rate generator or an external clock input from the SCK pin can be selected by clearing or setting the CKE1 bit in the serial control register (SCR). See table 12-9. When the SCI operates on an internal clock, it outputs the clock signal at the SCK pin. Eight clock pulses are output per transmitted or received character. When the SCI is not transmitting or receiving, the clock signal remains in the high state.

(3) Transmitting and Receiving Data

SCI Initialization (Clocked Synchronous Mode): Before transmitting or receiving, software must clear the TE and RE bits to 0 in the serial control register (SCR), then initialize the SCI as follows.

When changing the communication mode or format, always clear the TE and RE bits to 0 before following the procedure given below. Clearing TE to 0 sets TDRE to 1 and initializes the transmit shift register (TSR). Clearing RE to 0, however, does not initialize the RDRF, PER, FER, and ORER flags and receive data register (RDR), which retain their previous contents.

Figure 12-10 is a sample flowchart for initializing the SCI.

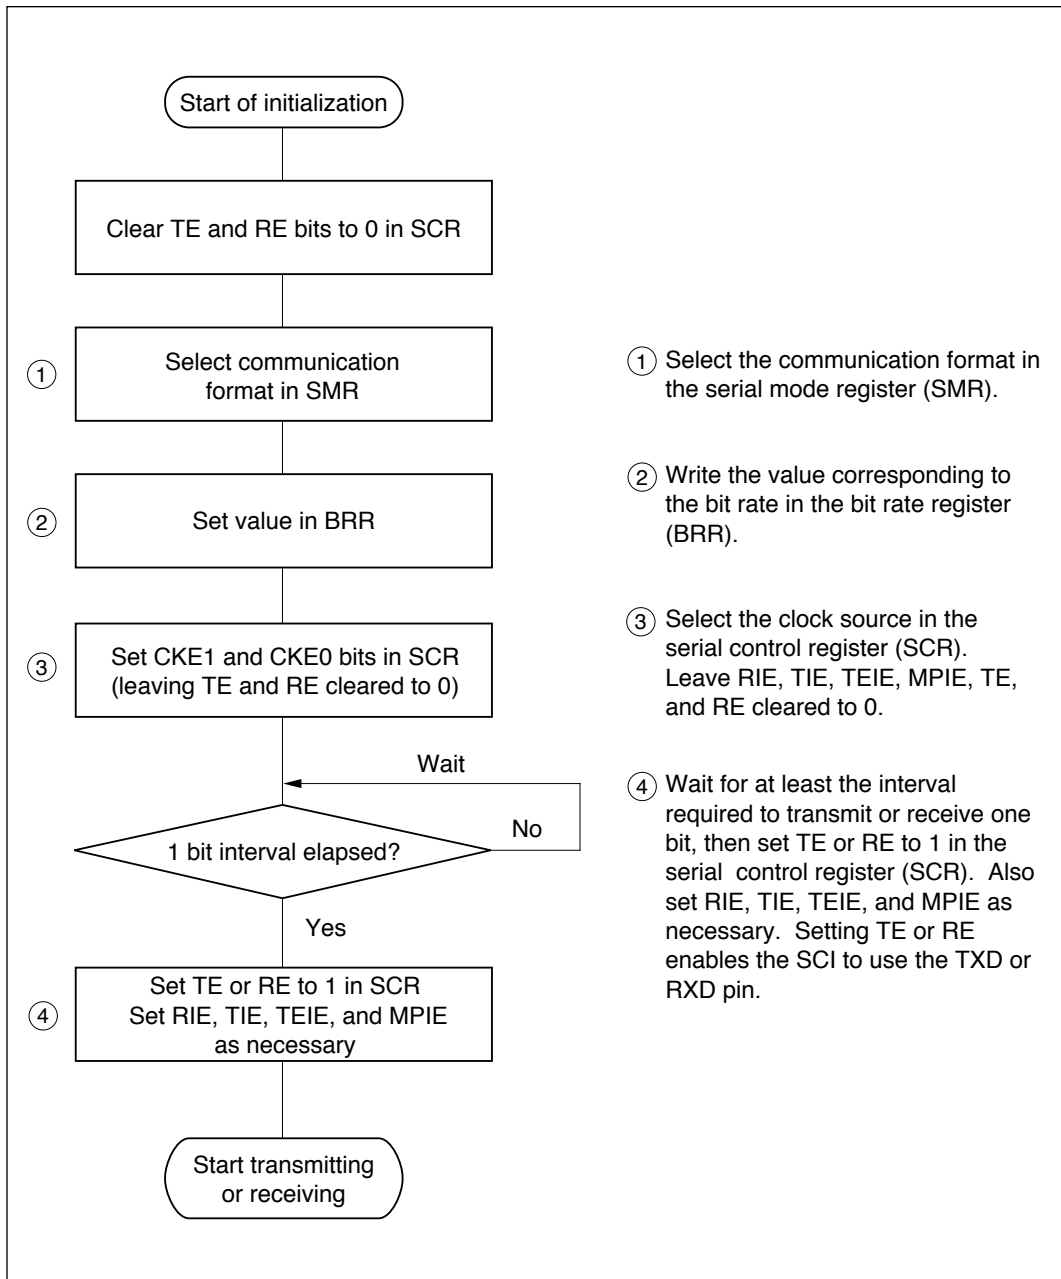

Figure 12-10 Sample Flowchart for SCI Initialization

Transmitting Serial Data (Clocked Synchronous Mode): Figure 12-11 shows a sample flowchart for transmitting serial data and indicates the procedure to follow.

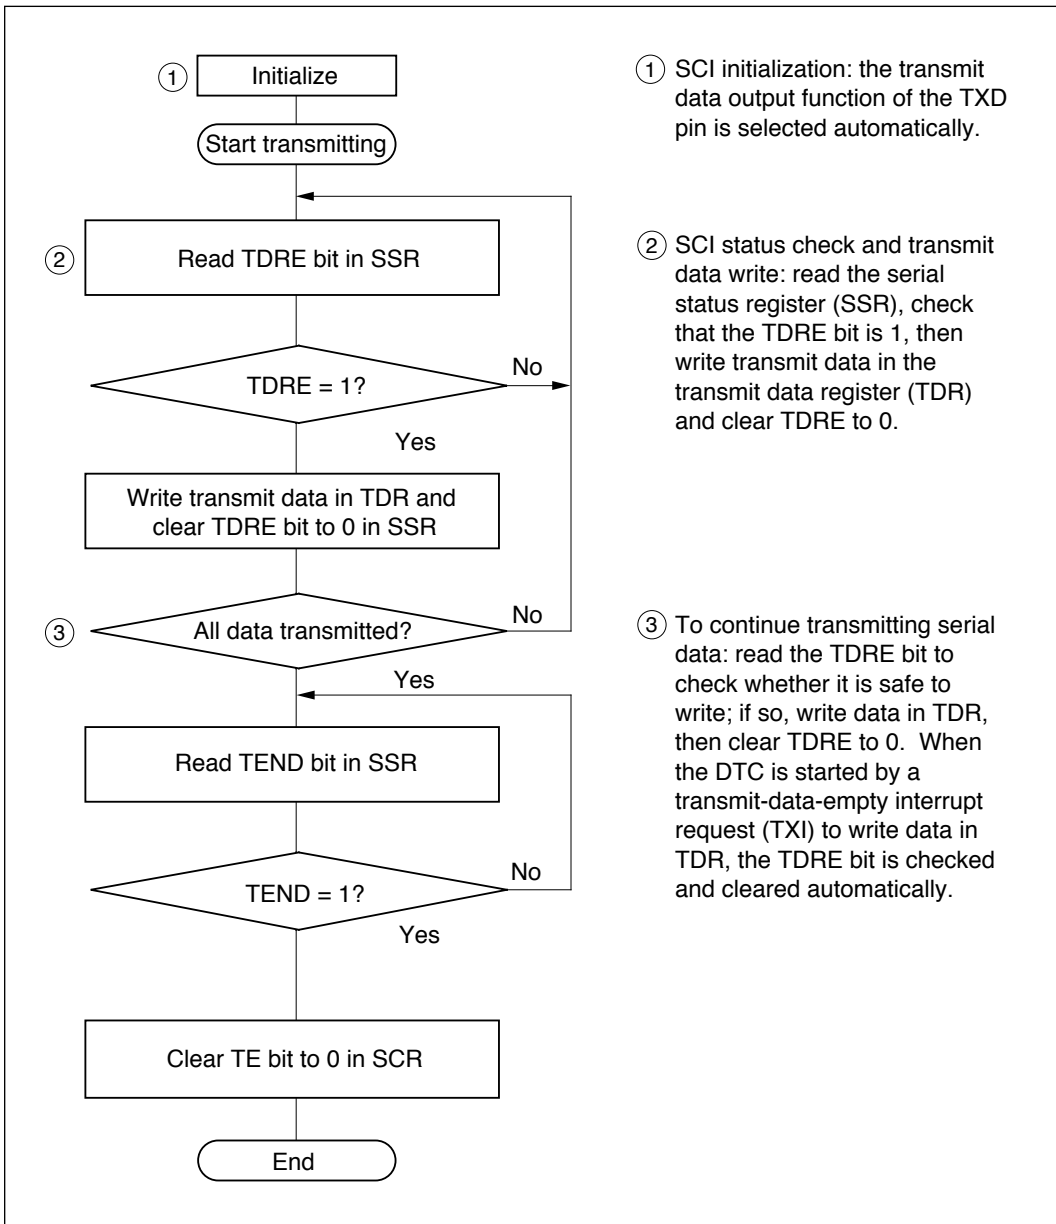

Figure 12-11 Sample Flowchart for Serial Transmitting

In transmitting serial data, the SCI operates as follows.

1. The SCI monitors the TDRE bit in SSR. When TDRE is cleared to 0 the SCI recognizes that the transmit data register (TDR) contains new data, and loads this data from TDR into the transmit shift register (TSR).
2. After loading the data from TDR into TSR, the SCI sets the TDRE bit to 1 and starts transmitting. If the transmit-data-empty interrupt enable bit (TIE) in SCR is set to 1, the SCI requests a transmit-data-empty interrupt (TXI) at this time.

If clock output is selected, the SCI outputs eight serial clock pulses. If an external clock source is selected, the SCI outputs data in synchronization with the input clock. Data are output from the TXD pin in order from LSB (bit 0) to MSB (bit 7).

3. The SCI checks the TDRE bit when it outputs the MSB (bit 7). If TDRE is 0, the SCI loads data from TDR into TSR and begins serial transmission of the next frame. If TDRE is 1, the SCI sets the TEND bit in SSR to 1, and after transmitting the MSB, holds the transmit data pin (TXD) in the MSB state. If the transmit-end interrupt enable bit (TEIE) in SCR is set to 1, a transmit-end interrupt (TEI) is requested at this time.
4. After the end of serial transmission, the SCK pin is held in the high state.

Figure 12-12 shows an example of SCI transmit operation.

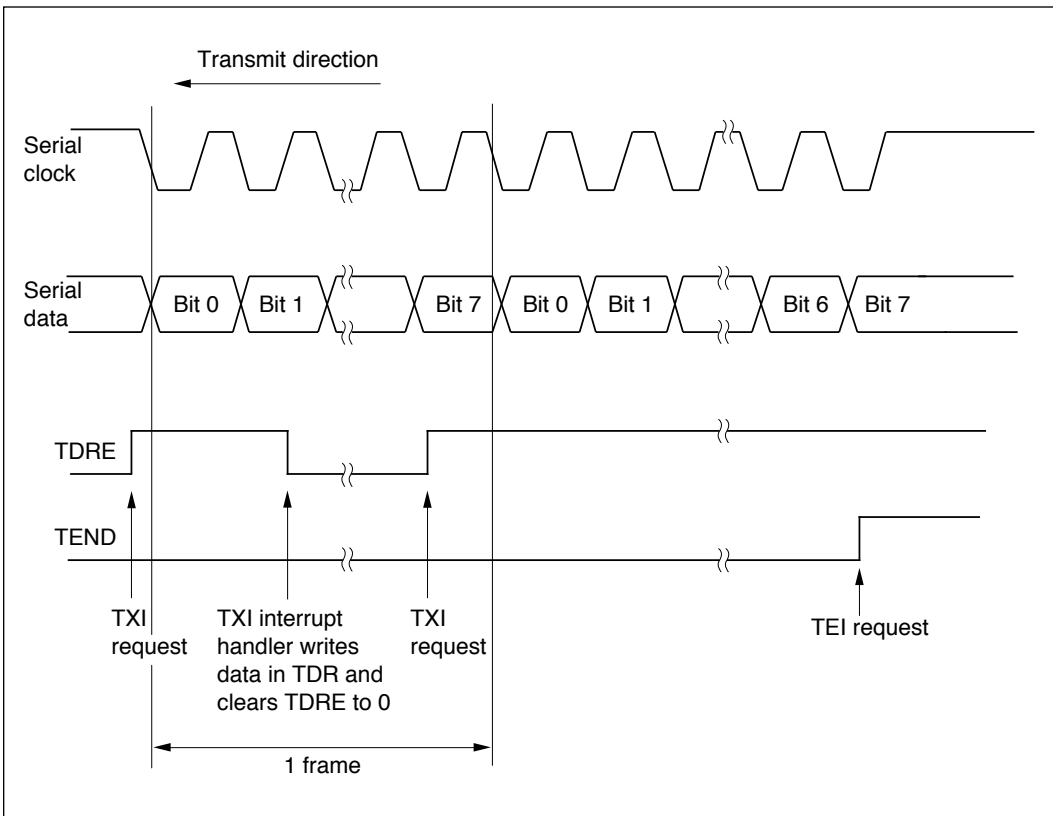

Figure 12-12 Example of SCI Transmit Operation

Receiving Serial Data (Clocked Synchronous Mode): Figure 12-13 shows a sample flowchart for receiving serial data and indicates the procedure to follow. When switching from asynchronous mode to clocked synchronous mode, make sure that ORER, PER, and FER are cleared to 0. If ORER, PER, or FER is set to 1 the RDRF bit will not be set and both transmitting and receiving will be disabled.

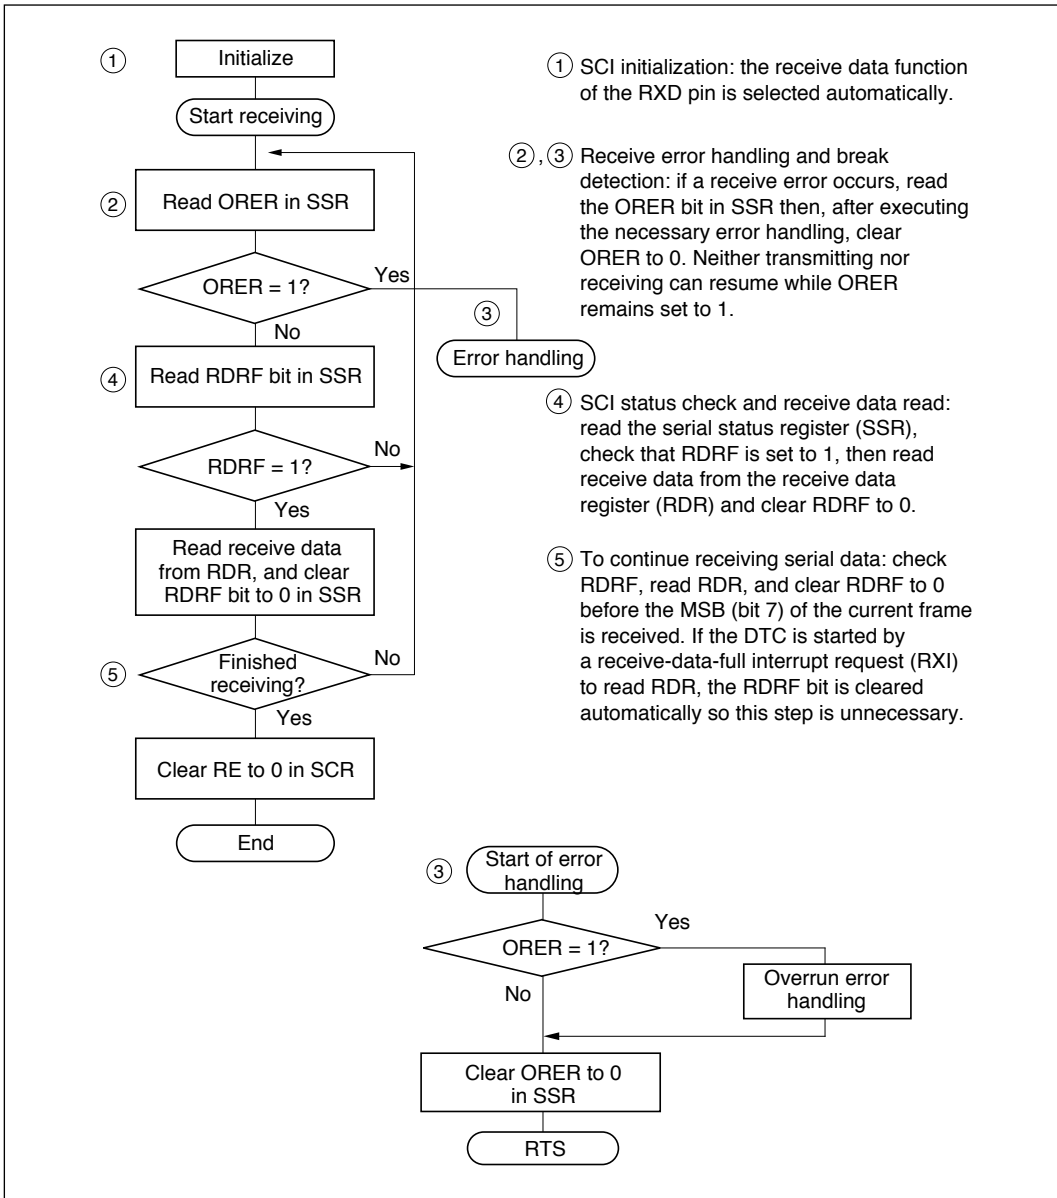

Figure 12-13 Sample Flowchart for Serial Receiving

In receiving, the SCI operates as follows.

1. The SCI synchronizes with serial clock input or output and initializes internally.
2. Receive data are shifted into RSR in order from LSB to MSB.

After receiving the data, the SCI checks that RDRF is 0 so that receive data can be loaded from RSR into RDR. If this check passes, the SCI sets RDRF to 1 and stores the received data in RDR. If the check does not pass (receive error), the SCI operates as indicated in table 12-11.

Note: Both transmitting and receiving are disabled while a receive error flag is set. The RDRF bit is not set to 1. Be sure to clear the error flag.

3. After setting RDRF to 1, if the receive-data-full interrupt enable bit (RIE) is set to 1 in SCR, the SCI requests a receive-data-full interrupt (RXI). If the ORER bit is set to 1 and the receive-data-full interrupt enable bit (RIE) in SCR is also set to 1, the SCI requests a receive-error interrupt (ERI).

Figure 12-14 shows an example of SCI receive operation.

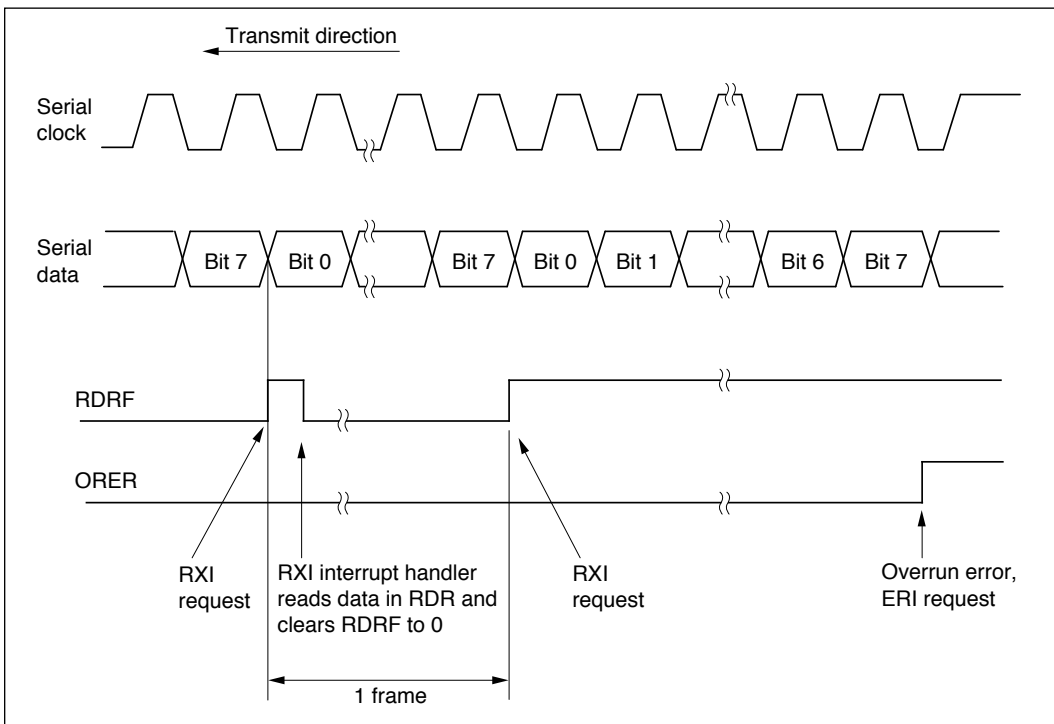

Figure 12-14 Example of SCI Receive Operation

Transmitting and Receiving Serial Data Simultaneously (clocked synchronous mode): Figure 12-15 shows a sample flowchart for transmitting and receiving serial data simultaneously and indicates the procedure to follow.

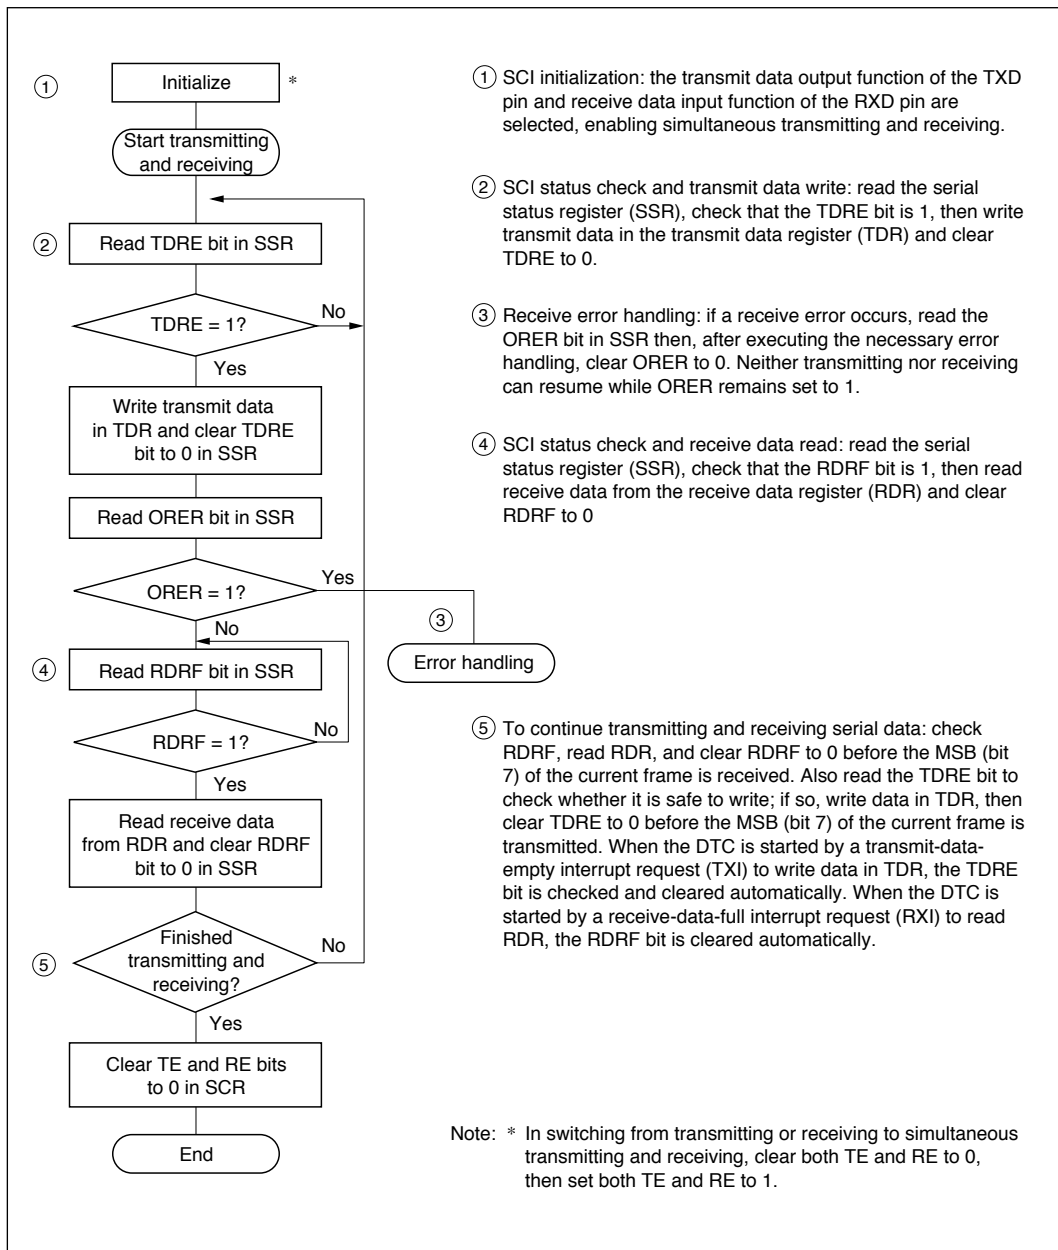

Figure 12-15 Sample Flowchart for Simultaneous Transmitting and Receiving

12.3.4 Multiprocessor Communication

The multiprocessor communication function enables several processors to share a single serial communication line. The processors communicate in asynchronous mode using a format with an additional multiprocessor bit (multiprocessor format).

In multiprocessor communication, each receiving processor is addressed by an ID. A serial communication cycle consists of an ID-sending cycle that identifies the receiving processor, and a data-sending cycle. The multiprocessor bit distinguishes ID-sending cycles from data-sending cycles.

The transmitting processor should start by sending the ID of the receiving processor with which it wants to communicate as data with the multiprocessor bit set to 1. Next the transmitting processor should send transmit data with the multiprocessor bit cleared to 0.

When a receiving processor receives data with the multiprocessor bit set to 1, if multiprocessor interrupts are enabled, an interrupt is requested. The interrupt-handling routine should compare the data with the processor's own ID. If the ID matches, the processor should continue to receive data. If the ID does not match, the processor should skip further incoming data until it again receives data with the multiprocessor bit set to 1. Multiple processors can send and receive data in this way.

Figure 12-16 shows an example of communication among different processors using a multiprocessor format.

(1) Communication Formats: Four formats are available. Parity-bit settings are ignored when a multiprocessor format is selected. For details see table 12-8.

(2) Clock: See the description of asynchronous mode.

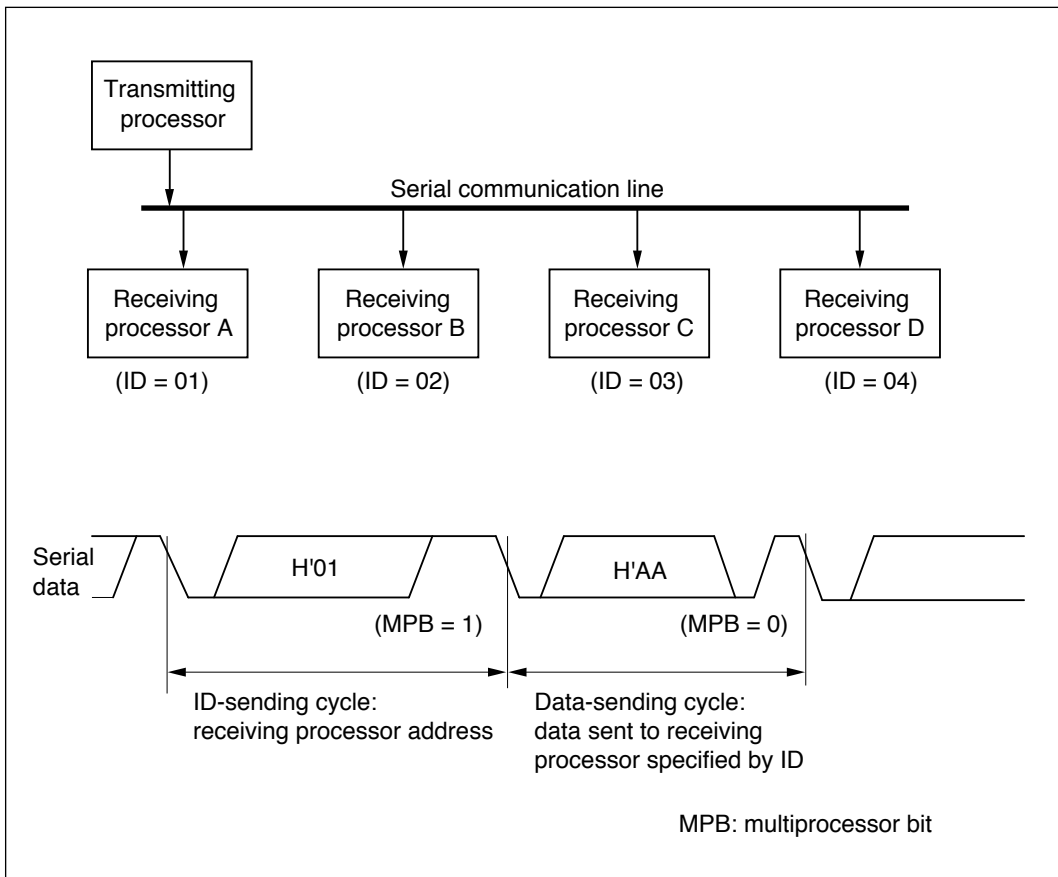

Figure 12-16 Example of Communication among Processors using Multiprocessor Format (Sending Data H'AA to Receiving Processor A)

(3) Transmitting and Receiving Data

Transmitting Multiprocessor Serial Data: Figure 12-17 shows a sample flowchart for transmitting multiprocessor serial data and indicates the procedure to follow.

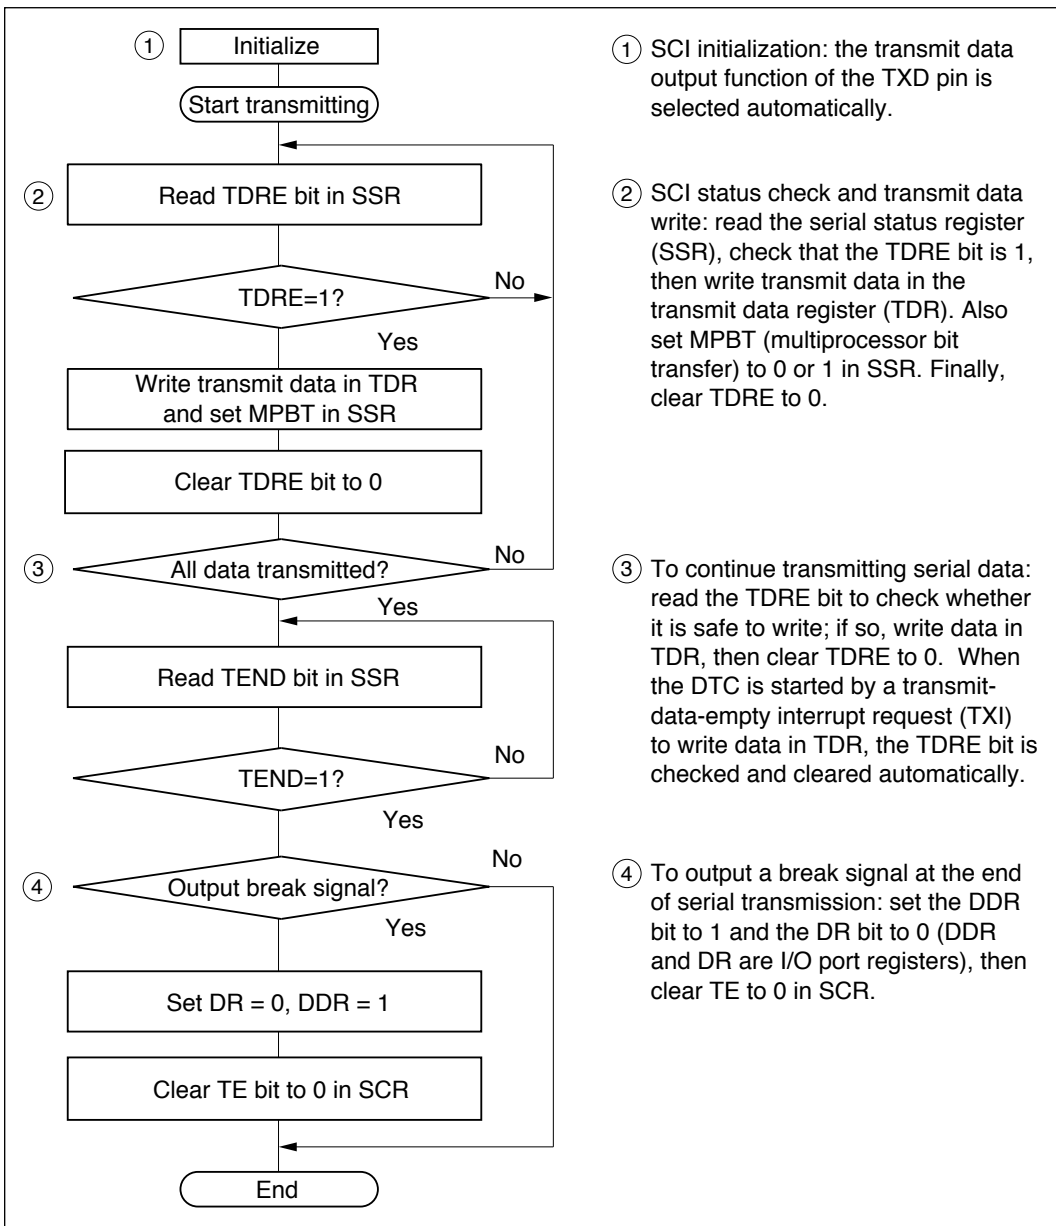

Figure 12-17 Sample Flowchart for Transmitting Multiprocessor Serial Data

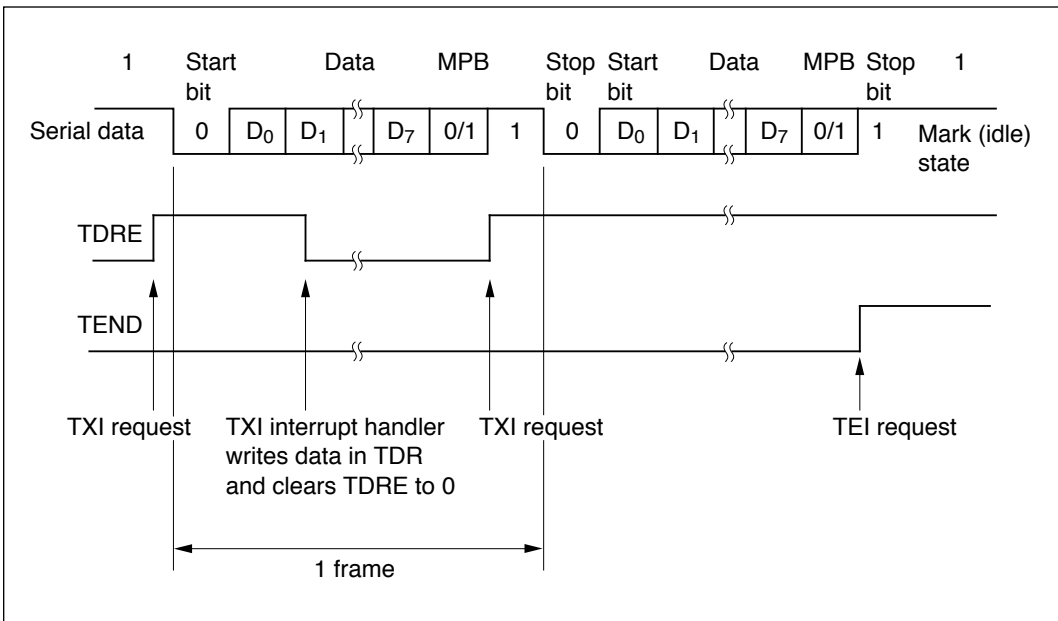

In transmitting serial data, the SCI operates as follows.

1. The SCI monitors the TDRE bit in SSR. When TDRE is cleared to 0 the SCI recognizes that the transmit data register (TDR) contains new data, and loads this data from TDR into the transmit shift register (TSR).
2. After loading the data from TDR into TSR, the SCI sets the TDRE bit to 1 and starts transmitting. If the transmit-data-empty interrupt enable bit (TIE) in SCR is set to 1, the SCI requests a transmit-data-empty interrupt (TXI) at this time.

Serial transmit data are transmitted in the following order from the TXD pin:

- a. Start bit: one 0 bit is output.
 - b. Transmit data: seven or eight bits are output, LSB first.
 - c. Multiprocessor bit: one multiprocessor bit (MPBT value) is output.
 - d. Stop bit: one or two 1 bits (stop bits) are output.
 - e. Mark state: output of 1 bits continues until the start bit of the next transmit data.
3. The SCI checks the TDRE bit when it outputs the stop bit. If TDRE is 0, the SCI loads data from TDR into TSR, outputs the stop bit, then begins serial transmission of the next frame. If TDRE is 1, the SCI sets the TEND bit in SSR to 1, outputs the stop bit, then continues output of 1 bits in the mark state. If the transmit-end interrupt enable bit (TEIE) in SCR is set to 1, a transmit-end interrupt (TEI) is requested at this time.

Figure 12-18 shows an example of SCI transmit operation using a multiprocessor format.

**Figure 12-18 Example of SCI Transmit Operation
(8-Bit Data with Multiprocessor Bit and One Stop Bit)**

Receiving Multiprocessor Serial Data: Figure 12-19 shows a sample flowchart for receiving multiprocessor serial data and indicates the procedure to follow.

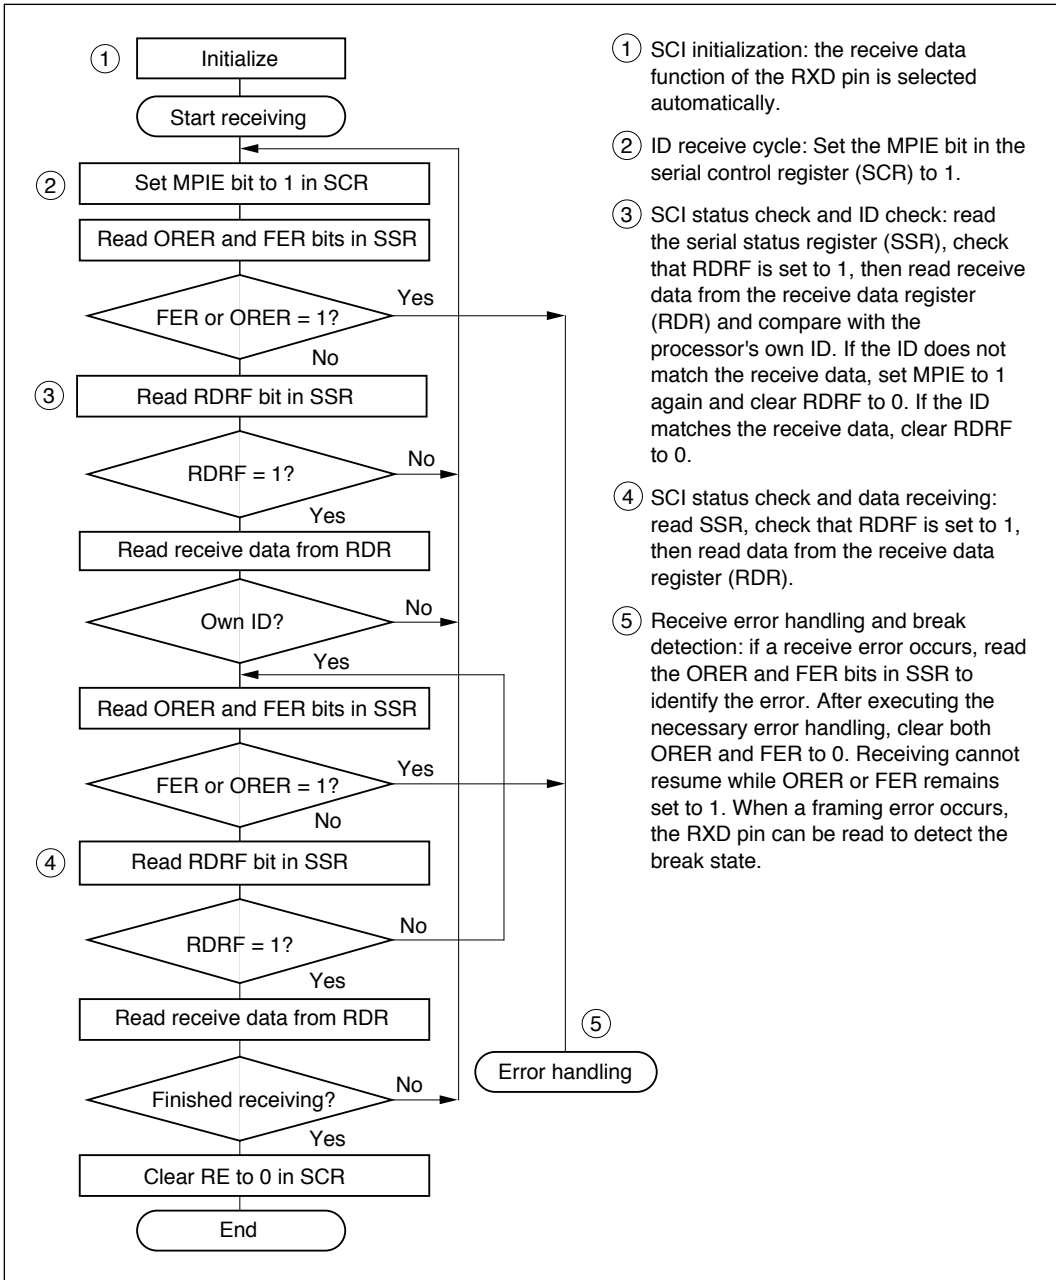

Figure 12-19 Sample Flowchart for Receiving Multiprocessor Serial Data

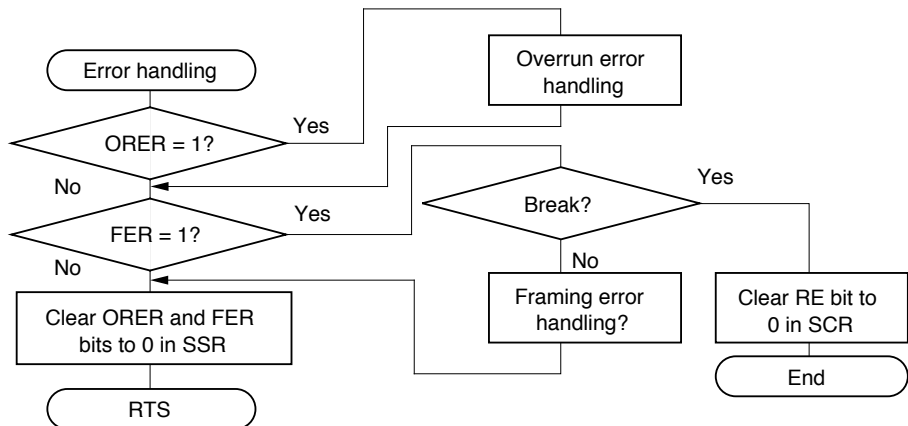

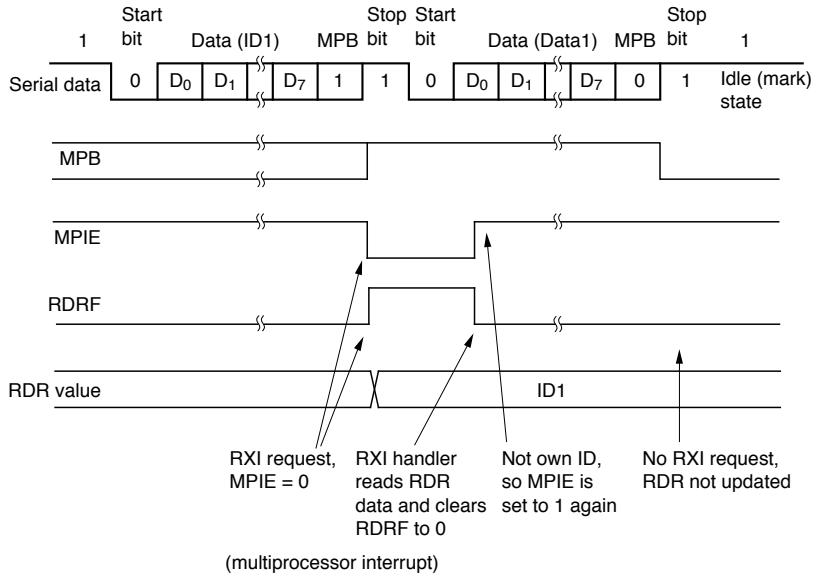

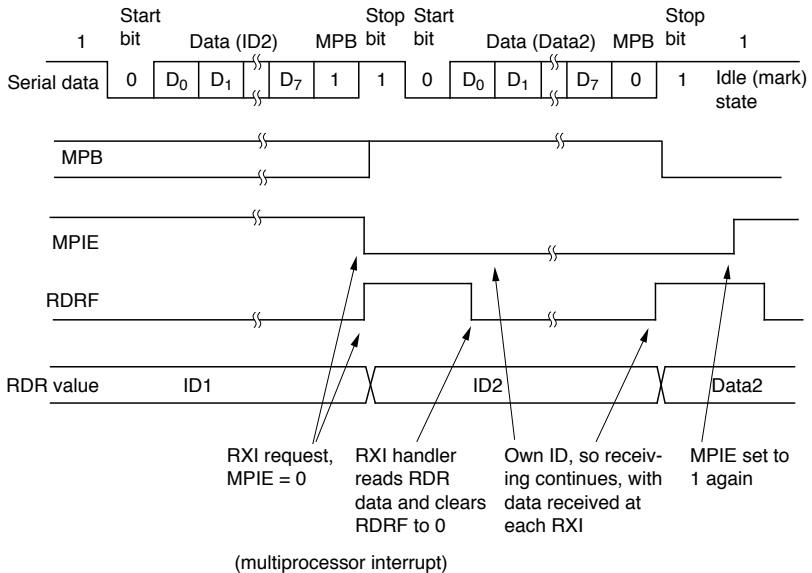

Figure 12-19 Sample Flowchart for Receiving Multiprocessor Serial Data (cont)

Figure 12-20 shows an example of SCI receive operation using a multiprocessor format.

a. Own ID does not match data

b. Own ID matches data

**Figure 12-20 Example of SCI Receive Operation
(Eight-Bit Data with Multiprocessor Bit and One Stop Bit)**

12.4 Interrupts and DTC

The SCI has four interrupt sources in each channel: transmit-end (TEI), receive-error (ERI), receive-data-full (RXI), and transmit-data-empty (TXI). Table 12-12 lists the interrupt sources and indicates their priority.

Table 12-12 SCI Interrupt Sources

Interrupt Source	Description	DTC Availability	Priority
ERI	Receive error (ORER, PER, or FER)	No	High ↑ ↓ Low
RXI	Receive data register full (RDRF)	Yes	
TXI	Transmit data register empty (TDRE)	Yes	
TEI	Transmit end (TEND)	No	Low

These interrupts can be enabled and disabled by the TIE and RIE bits in the serial control register (SCR). Each interrupt request is sent separately to the interrupt controller. TXI is requested when the TDRE bit in SSR is set to 1. TEI is requested when the TEND bit in SSR is set to 1. TXI can start the data transfer controller (DTC) to transfer data. TDRE is automatically cleared to 0 when the DTC executes the data transfer. TEI cannot start the DTC.

RXI is requested when the RDRF bit in SSR is set to 1. ERI is requested when the ORER, PER, or FER bit in SSR is set to 1. RXI can start the DTC to transfer data. RDRF is automatically cleared to 0 when the DTC executes the data transfer. ERI cannot start the DTC.

12.5 Usage Notes

Note the following points when using the SCI.

(1) TDR Write and TDRE: The TDRE bit in the serial status register (SSR) is a status flag indicating loading of transmit data from TDR into TSR. The SCI sets TDRE to 1 when it transfers data from TDR to TSR.

Data can be written into TDR regardless of the state of TDRE. If new data are written in TDR when TDRE is 0, the old data stored in TDR will be lost because these data have not yet been transferred to TSR. Before writing transmit data to TDR, be sure to check that TDRE is set to 1.

(2) Simultaneous Multiple Receive Errors: Table 12-13 indicates the state of SSR status flags when multiple receive errors occur simultaneously. When an overrun error occurs the RSR contents are not transferred to RDR, so receive data are lost.

Table 12-13 SSR Status Flags and Transfer of Receive Data

SSR Status Flags				Receive Data Transfer	
RDRF	ORER	FER	PER	RSR → RDR	Receive Errors
1	1	0	0	×	Overrun error
0	0	1	0	○	Framing error
0	0	0	1	○	Parity error
1	1	1	0	×	Overrun error + framing error
1	1	0	1	×	Overrun error + parity error
0	0	1	1	○	Framing error + parity error
1	1	1	1	×	Overrun error + framing error + parity error

○: Receive data are transferred from RSR to RDR.

×: Receive data are not transferred from RSR to RDR.

(3) Break Detection and Processing: Break signals can be detected by reading the RXD pin directly when a framing error (FER) is detected. In the break state the input from the RXD pin consists of all 0s, so FER is set and the parity error flag (PER) may also be set. In the break state the SCI receiver continues to operate, so if the FER bit is cleared to 0 it will be set to 1 again.

(4) Sending a Break Signal: When TE is cleared to 0 the TXD pin becomes an I/O port, the level and direction (input or output) of which are determined by the DR and DDR bits. This feature can be used to send a break signal.

After the serial transmitter is initialized, the DR value substitutes for the mark state until TE is set to 1 (the TXD pin function is not selected until TE is set to 1). The DDR and DR bits should therefore both be set to 1 beforehand.

To send a break signal during serial transmission, clear the DR bit to 0, then clear TE to 0. When TE is cleared to 0 the transmitter is initialized, regardless of its current state, so the TXD pin becomes an output port outputting the value 0.

(5) Receive Error Flags and Transmitter Operation (clocked synchronous mode only):

When a receive error flag (ORER, PER, or FER) is set to 1, the SCI will not start transmitting even if TE is set to 1. Be sure to clear the receive error flags to 0 when starting to transmit. Note that clearing RE to 0 does not clear the receive error flags.

(6) Receive Data Sampling Timing in Asynchronous Mode and Receive Margin:

In asynchronous mode the SCI operates on an base clock with 16 times the bit rate frequency. In receiving, the SCI synchronizes internally with the falling edge of the start bit, which it samples on the base clock. Receive data are latched on the rising edge of the eighth base clock pulse. See figure 12-21.

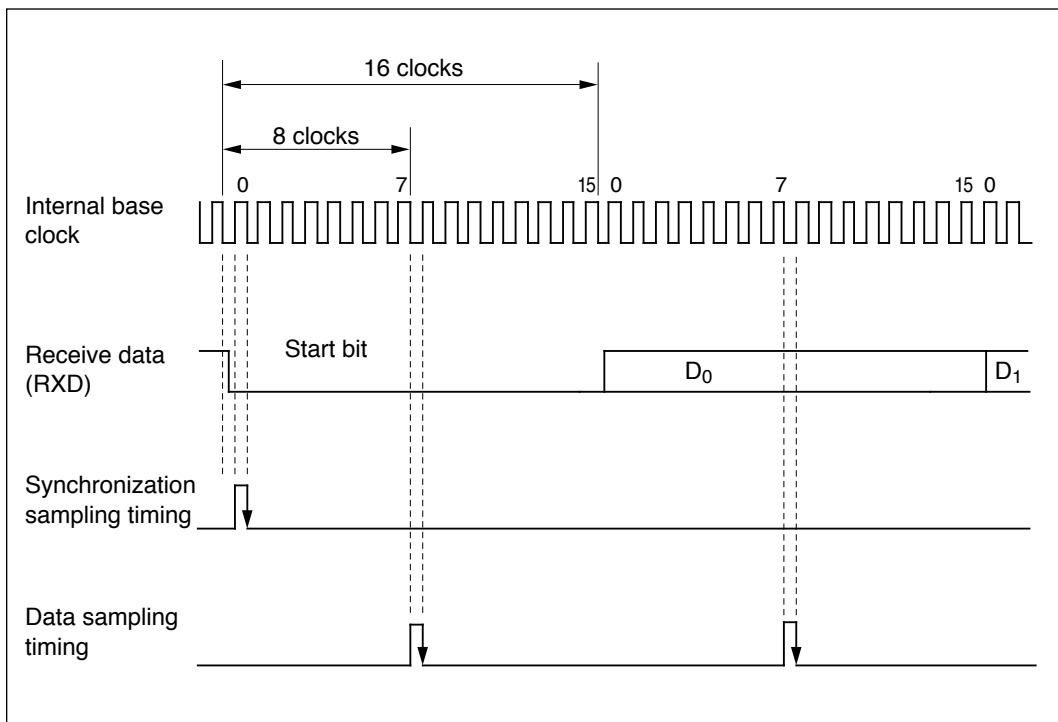

Figure 12-21 Receive Data Sampling Timing in Asynchronous Mode

The receive margin in asynchronous mode can therefore be expressed as in equation (1).

$$M = \left\{ \left(0.5 - \frac{1}{2N} \right) - \left(L - 0.5 - \frac{1}{2N} \right) F - \frac{|D - 0.5|}{N} (1 + F) \right\} \times 100\% \quad \text{..... (1)}$$

M: Receive margin (%)

N: Ratio of clock frequency to bit rate (N = 16)

D: Clock duty cycle (D = 0 to 1.0)

L: Frame length (L = 9 to 12)

F: Absolute deviation of clock frequency

From equation (1), if F = 0 and D = 0.5 the receive margin is 46.875%, as given by equation (2).

$$D = 0.5, F = 0$$

$$M = \left(0.5 - \frac{1}{2 \times 16} \right) \times 100\% \\ = 46.875\% \quad \text{..... (2)}$$

This is a theoretical value. A reasonable margin to allow in system designs is 20 to 30%.

Section 13 A/D Converter

13.1 Overview

The H8/538F chip includes a 10-bit successive-approximations A/D converter. Software can select a maximum of 12 analog input channels.

13.1.1 Features

A/D converter features are listed below.

- Ten-bit resolution
Number of input channels: 12
- High-speed conversion
Conversion time: minimum 13.4 μ s per channel (10 MHz system clock)
- Two conversion modes
Single mode: A/D conversion of one channel
Scan mode: continuous conversion on one to 12 channels
- Twelve 10-bit A/D data registers
A/D conversion results are transferred for storage into 12 A/D data registers. Each channel has its own A/D data register.
- Built-in sample-and-hold function
A sample-and-hold circuit is built into the A/D converter, permitting a simplified external analog input circuit.
- A/D conversion interrupt with DTC (data transfer controller) support
At the end of A/D conversion, an A/D end interrupt request (ADI) can be sent to the H8/500 CPU. The ADI interrupt can also be served by the DTC.
- External triggering
A/D conversion can be started by an external trigger signal.
- Selectable analog conversion voltage range
The analog voltage conversion range can be set from 3.5 to 5.5 V by input at the V_{REF} pin.
- A/D conversion can also be started by the IPU.

13.1.2 Block Diagram

Figure 13-1 shows a block diagram of the A/D converter.

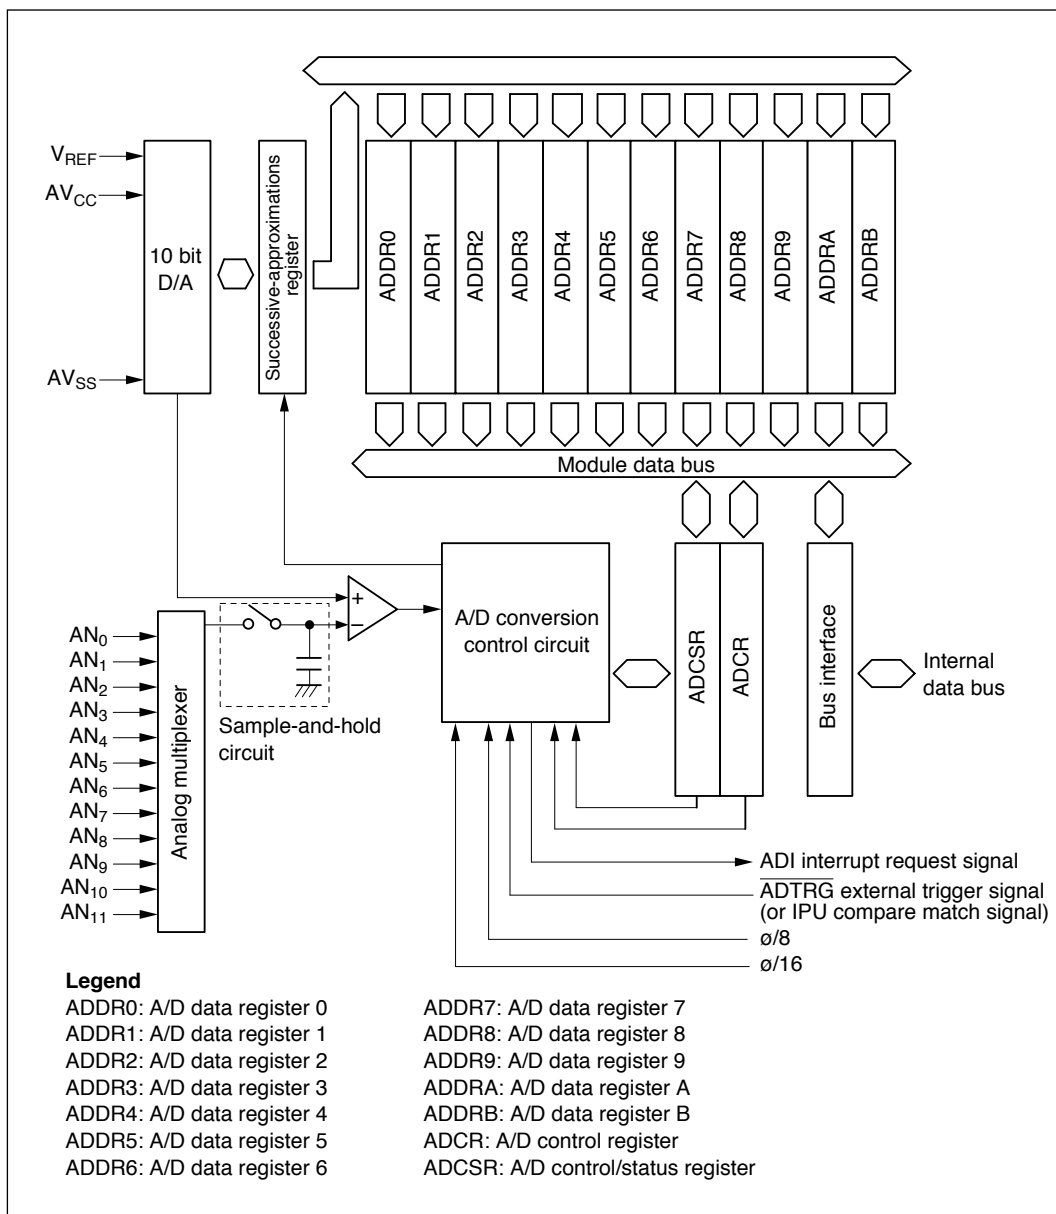

Figure 13-1 A/D Converter Block Diagram

13.1.3 Input/Output Pins

Table 13-1 summarizes the A/D converter's input pins. The 12 analog input pins (AN_0 to AN_{11}) are divided into three groups: AN_0 to AN_3 (group 0), AN_4 to AN_7 (group 1), and AN_8 to AN_{11} (group 2). The \overline{ADTRG} pin can trigger the start of A/D conversion externally. The A/D converter starts A/D conversion when a low pulse is applied to this pin. AV_{CC} and AV_{SS} are the power supply for the analog circuits in the A/D converter. V_{REF} is a conversion reference voltage.

To protect the reliability of the chip, AV_{CC} , AV_{SS} , V_{CC} , and V_{SS} should be related as follows: $AV_{CC} = V_{CC} \pm 10\%$; $AV_{SS} = V_{SS}$. AV_{CC} and AV_{SS} must not be left open, even if the A/D converter is not used. Voltages applied to the analog input pins should be in the range $AV_{SS} \leq AN_n \leq V_{REF}$.

Table 13-1 A/D Converter Pins

Pin Name	Abbreviation	Input/Output	Function
Analog power supply	AV_{CC}	Input	Analog power supply
Analog ground	AV_{SS}	Input	Analog ground and reference voltage
Reference voltage	V_{REF}	Input	Analog reference voltage
Analog input 0	AN_0	Input	Analog input pins 0 to 3 (analog group 0)
Analog input 1	AN_1	Input	
Analog input 2	AN_2	Input	
Analog input 3	AN_3	Input	
Analog input 4	AN_4	Input	Analog input pins 4 to 7 (analog group 1)
Analog input 5	AN_5	Input	
Analog input 6	AN_6	Input	
Analog input 7	AN_7	Input	
Analog input 8	AN_8	Input	Analog input pins 8 to 11 (analog group 2)
Analog input 9	AN_9	Input	
Analog input 10	AN_{10}	Input	
Analog input 11	AN_{11}	Input	
A/D trigger	$ADTRG$	Input	External trigger pin for A/D conversion

13.1.4 Register Configuration

Table 13-2 summarizes the A/D converter's registers.

Table 13-2 A/D Converter Registers

Address	Name	Abbreviation	R/W	Initial Value
H'FEA0	A/D data register 0 (high/low)	ADDR0(H/L)	R	H'0000
H'FEA2	A/D data register 1 (high/low)	ADDR1(H/L)	R	H'0000
H'FEA4	A/D data register 2 (high/low)	ADDR2(H/L)	R	H'0000
H'FEA6	A/D data register 3 (high/low)	ADDR3(H/L)	R	H'0000
H'FEA8	A/D data register 4 (high/low)	ADDR4(H/L)	R	H'0000
H'FEAA	A/D data register 5 (high/low)	ADDR5(H/L)	R	H'0000
H'FEAC	A/D data register 6 (high/low)	ADDR6(H/L)	R	H'0000
H'FEAE	A/D data register 7 (high/low)	ADDR7(H/L)	R	H'0000
H'FEB0	A/D data register 8 (high/low)	ADDR8(H/L)	R	H'0000
H'FEB2	A/D data register 9 (high/low)	ADDR9(H/L)	R	H'0000
H'FEB4	A/D data register A (high/low)	ADDRA(H/L)	R	H'0000
H'FEB6	A/D data register B (high/low)	ADDRB(H/L)	R	H'0000
H'FEB8	A/D control/status register	ADCSR	R/W*	H'00
H'FEB9	A/D control register	ADCR	R/W	H'1F

Note: * Software can write 0 in bit 7 of the A/D control/status register (ADCSR) to clear the flag, but cannot write 1.

13.2 Register Descriptions

13.2.1 A/D Data Registers 0 to B

A/D data registers 0 to B (ADDR0 to ADDR_B) are 16-bit read-only registers that store the results of A/D conversion of the analog inputs. There are 12 registers, corresponding to analog inputs 0 to 11 (AN₀ to AN₁₁). The A/D data registers are initialized to H'0000 by a reset and in the standby modes.

Bit	7	6	5	4	3	2	1	0
ADDRnH (upper byte)	AD9	AD8	AD7	AD6	AD5	AD4	AD3	AD2
Initial value	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Bit	7	6	5	4	3	2	1	0
ADDRnL (lower byte)	AD1	AD0	—	—	—	—	—	—
Initial value	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

(n = 0 to B)

The H8/538F's A/D converter converts the analog inputs to 10-bit digital values. The upper eight of the 10 bits are stored in the upper byte of the A/D data register of the selected channel. The lower two bits are stored in the lower byte of the A/D data register. Only the two upper bits of the lower byte of an A/D data register are valid. Table 13-3 indicates the pairings of analog input channels and A/D data registers.

The H8/500 CPU can always read and write the A/D data registers. The upper byte must always be read before the lower byte. It is possible to read only the upper byte of an A/D data register, but it is not possible to read only the lower byte. For further details see section 13.3, "H8/500 CPU Interface." Bits 5 to 0 of the A/D data registers are reserved bits that cannot be modified and always read 0.

Table 13-3 Analog Input Channels and A/D Data Registers

Analog Input Channel	A/D Data Register	Analog Input Channel	A/D Data Register	Analog Input Channel	A/D Data Register
AN ₀	ADDR0	AN ₄	ADDR4	AN ₈	ADDR8
AN ₁	ADDR1	AN ₅	ADDR5	AN ₉	ADDR9
AN ₂	ADDR2	AN ₆	ADDR6	AN ₁₀	ADDRA
AN ₃	ADDR3	AN ₇	ADDR7	AN ₁₁	ADDRB

13.2.2 A/D Control Status Register

The A/D control status register (ADCSR) is an eight-bit readable/writable register that selects the A/D conversion mode. ADCSR is initialized to H'00 by a reset and in the standby modes.

Bit	7	6	5	4	3	2	1	0
	ADF	ADIE	ADM1	ADM0	CH3	CH2	CH1	CH0
Initial value	0	0	0	0	0	0	0	0
R/W	R/(W)*	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Channel select 3–0
These bits select analog input channels

A/D mode 1/0
These bits select the A/D conversion mode (single and scan modes)

A/D interrupt enable
Enables and disables A/D end interrupts

A/D end flag
Indicates end of A/D conversion

Note: * Software can write 0 to clear the flag but cannot write 1.

(1) Bit 7—A/D End Flag (ADF): Indicates the end of A/D conversion. ADF is initialized to 0 by a reset and in the standby modes.

Bit 7

ADF	Description
0	A/D conversion is in progress or the A/D converter is idle (Initial value) ADF is cleared to 0 when: 1. Software reads ADF after it has been set to 1, then writes 0 in ADF 2. The DTC is started by ADI
1	A/D conversion has ended and a digital value has been loaded into one or more A/D data registers ADF is set to 1 when: 1. A/D conversion ends in single mode 2. All conversion in one selected analog group ends

After ADF is set to 1, the A/D converter operates differently in single mode and scan mode. In single mode, after loading a digital value into an A/D data register, the A/D converter sets ADF to 1 then goes into the idle state. In scan mode, after completing all conversion in one selected analog group, the A/D converter sets ADF to 1 then continues converting.

Software cannot write 1 in ADF.

(2) Bit 6—A/D Interrupt Enable (ADIE): Enables or disables the A/D end interrupt (ADI). ADIE is initialized to 0 by a reset and in the standby modes.

Bit 6

ADIE	Description
0	A/D end interrupt (ADI) is disabled (Initial value)
1	A/D end interrupt (ADI) is enabled

When A/D conversion ends and the ADF bit in ADCSR is set to 1, if ADIE is also set to 1 an A/D end interrupt (ADI) is requested. The ADI interrupt request can be cleared by clearing ADF to 0 or clearing ADIE to 0.

(3) Bits 5 and 4—A/D Mode 1/0 (ADM1/0): These bits select single mode, four-channel scan mode, eight-channel scan mode, or 12-channel scan mode as the A/D conversion mode. ADM1 and ADM0 are cleared to 00 by a reset and in the standby modes, selecting single mode. To ensure correct operation, always clear ADST to 0 before changing the conversion mode.

Bit 5	Bit 4	
ADM1	ADM0	Description
0	0	Single mode (Initial value)
0	1	Four-channel scan mode (analog group 0, 1, or 2)
1	0	Eight-channel scan mode (analog groups 0 and 1)
1	1	Twelve-channel scan mode (analog groups 0, 1, and 2)

When ADM1 and ADM0 are cleared to 00, single mode is selected. In single mode one analog channel is converted once. The channel is selected by bits CH3 to CH0 in ADCSR.

Setting ADM1 and ADM0 to 01 selects four-channel scan mode. In scan mode, one or more channels are converted continuously. The channels converted in scan mode are selected by bits CH3 to CH0 in ADCSR. In four-channel scan mode, A/D conversion is performed in the four channels in analog group 0 (AN_0 to AN_3), analog group 1 (AN_4 to AN_7), or analog group 2 (AN_8 to AN_{11}).

Setting ADM1 and ADM0 to 10 selects eight-channel scan mode. A/D conversion is performed in the eight channels in analog group 0 (AN_0 to AN_3) and analog group 1 (AN_4 to AN_7).

Setting ADM1 and ADM0 to 01 selects 12-channel scan mode. A/D conversion is performed in the 12 channels in analog group 0 (AN_0 to AN_3), analog group 1 (AN_4 to AN_7), and analog group 2 (AN_8 to AN_{11}).

For further details on operation in single and scan modes, see section 13.4, “Operation.”

(4) Bits 3 to 0—Channel Select 3 to 0 (CH3 to CH0): These bits and ADM1 and ADM0 select the analog input channels. CH3 to CH0 are initialized to 0000 by a reset and in the standby modes. To ensure correct operation, always clear ADST to 0 in the A/D control register (ADCR) before changing the analog input channel selection.

Bit 3	Bit 2	Bit 1	Bit 0	Analog Input Channels	
CH3	CH2	CH1	CH0	Single Mode	Four-Channel Scan Mode
0	0	0	0	AN ₀ (Initial value)	AN ₀
		0	1	AN ₁	AN _{0, 1}
		1	0	AN ₂	AN _{0–2}
		1	1	AN ₃	AN _{0–3}
	1	0	0	AN ₄	AN ₄
		0	1	AN ₅	AN _{4, 5}
		1	0	AN ₆	AN _{4–6}
		1	1	AN ₇	AN _{4–7}
1	0*1	0	0	AN ₈	AN ₈
		0	1	AN ₉	AN _{8, 9}
		1	0	AN ₁₀	AN _{8–10}
		1	1	AN ₁₁	AN _{8–11}

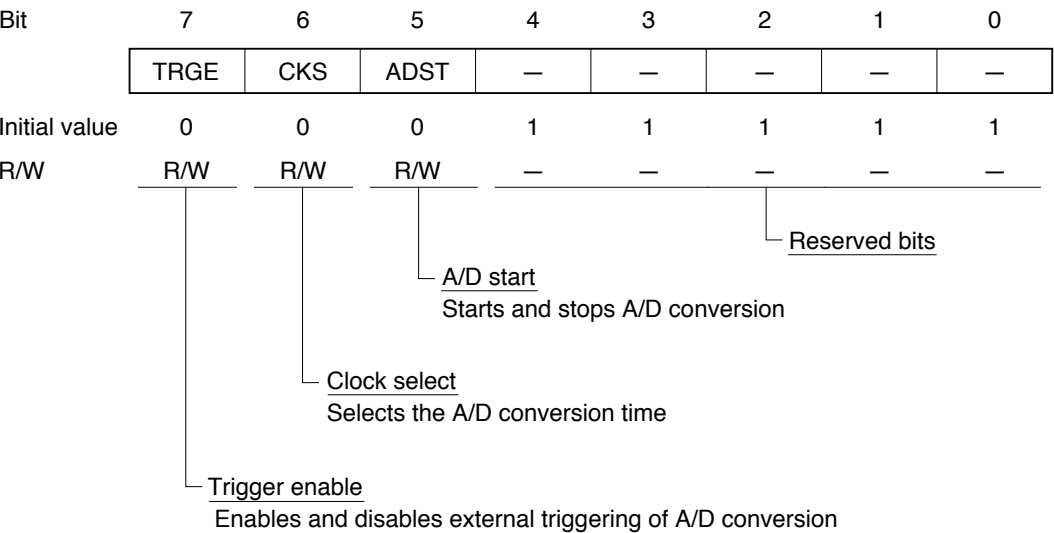

Bit 3	Bit 2	Bit 1	Bit 0	Analog Input Channels	
CH3	CH2	CH1	CH0	Eight-Channel Scan Mode	12-Channel Scan Mode
0	0	0	0	AN _{0, 4}	AN _{0, 4, 8}
		0	1	AN _{0, 1, 4, 5}	AN _{0, 1, 4, 5, 8, 9}
		1	0	AN _{0–2, 4–6}	AN _{0–2, 4–6, 8–10}
		1	1	AN _{0–7}	AN _{0–11}
	1	0	0	AN _{0, 4}	AN _{0, 4, 8}
		0	1	AN _{0, 1, 4, 5}	AN _{0, 1, 4, 5, 8, 9}
		1	0	AN _{0–2, 4–6}	AN _{0–2, 4–6, 8–10}
		1	1	AN _{0–7}	AN _{0–11}
1	0*1	0	0	Reserved*2	AN _{0, 4, 8}
		0	1		AN _{0, 1, 4, 5, 8, 9}
		1	0		AN _{0–2, 4–6, 8–10}
		1	1		AN _{0–11}

Notes: 1. Must be cleared to 0.

2. Reserved for future expansion. Must not be used.

13.2.3 A/D Control Register

The A/D control register (ADCR) is an eight-bit readable/writable register that controls the start of A/D conversion and selects the A/D clock. ADCR is initialized to H'1F by a reset and in the standby modes. Bits 4 to 0 of ADCR are reserved for future expansion. They cannot be modified and always read 1.

(1) **Bit 7—Trigger Enable (TRGE):** Enables or disables external triggering of A/D conversion. When TRGE is set to 1, P7₁ automatically becomes the $\overline{\text{ADTRG}}$ input pin. TRGE is initialized to 0 by a reset and in the standby modes.

Bit 7	
TRGE	Description
0	A/D conversion cannot be externally triggered (Initial value)
1	A/D conversion can be externally triggered (P7 ₁ is the $\overline{\text{ADTRG}}$ pin.)

After TRGE is set to 1, if a low pulse is input at the $\overline{\text{ADTRG}}$ pin, the A/D converter detects the falling edge of the pulse and sets the ADST bit in ADCR to 1. Subsequent operation is the same as if software had set the ADST bit to 1. External triggering operates only when the ADST bit is cleared to 0.

When the external trigger function is used, the low pulse input at the $\overline{\text{ADTRG}}$ pin must have a width of at least 1.5 system clocks (1.5 ϕ). For further details see section 13.4.4, “External Triggering of A/D Conversion.”

(2) Bit 6—Clock Select (CKS): Selects the A/D conversion time. A/D conversion is performed in 266 states when CKS is cleared to 0, or in 134 states when CKS is set to 1. CKS is initialized to 0 by a reset and in the standby modes. To ensure correct operation, always clear ADST to 0 before changing the A/D conversion time.

Bit 6

CKS	Description
0	Conversion time = 266 states (maximum) (Initial value)
1	Conversion time = 134 states (maximum)

(3) Bit 5—A/D Start (ADST): Starts and stops A/D conversion. A/D conversion starts when ADST is set to 1 and stops when ADST is cleared to 0. ADST is initialized to 0 by a reset and in the standby modes.

Bit 5

ADST	Description
0	A/D conversion is stopped (Initial value)
1	A/D conversion is in progress Clearing conditions: 1. Single mode: cleared to 0 automatically at the end of A/D conversion 2. Scan mode: check that ADF is set to 1 in ADCSR, then write 0 in ADST

The ADST bit operates differently in single and scan modes. In single mode, ADST is cleared to 0 automatically after A/D conversion of one channel. In scan mode, after all selected analog inputs have been converted A/D conversion of all these channels begins again, so ADST remains set to 1. When the conversion time or analog input channel selection is changed in scan mode, the ADST bit should first be cleared to 0 to halt A/D conversion.

Before changing the A/D conversion time (CKS bit in ADCR), operating mode (ADM1/0 bits in ADCSR), or analog input channel selection (bits CH3 to CH0 in ADCSR), always check that the A/D converter is stopped (ADST = 0). Making these changes while the A/D converter is operating (ADST = 1) may produce incorrect values in the A/D data registers.

(4) Bits 4 to 0—Reserved: These bits are reserved for future expansion. They cannot be modified and always read 1.

13.3 H8/500 CPU Interface

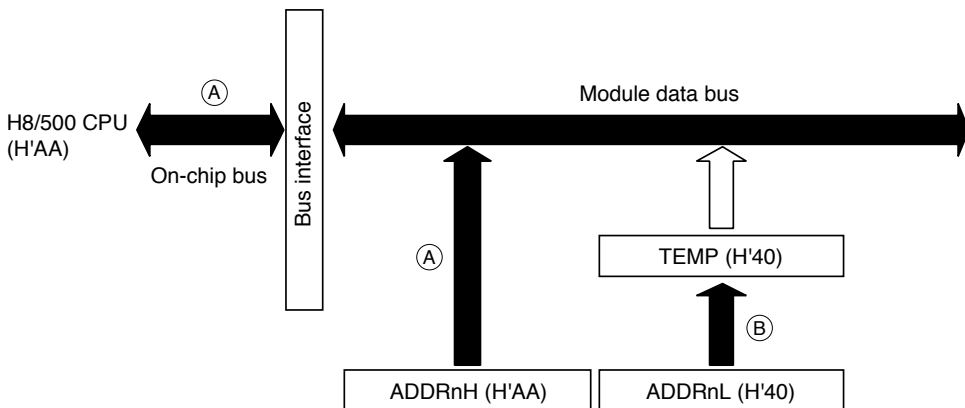

A/D data registers 0 to B (ADDR0 to ADDR B) are 16-bit registers, but they are connected to the H8/500 CPU via an eight-bit on-chip data bus. The upper and lower bytes of an A/D data register are necessarily read separately. To prevent data from changing between the reading of the upper and lower bytes of an A/D data register, the lower byte is read using a temporary register (TEMP). The upper byte can be read directly.

An A/D data register is read as follows. The upper byte must be read first. The H8/500 CPU receives the upper-byte data directly at this time. At the same time, the A/D converter transfers the lower-byte data internally into TEMP. Next, when the lower byte is read, the H8/500 CPU receives the contents of TEMP.

When reading an A/D data register using byte operand size, always read the upper byte before the lower byte. It is possible to read only the upper byte, but if only the lower byte is read incorrect data may be obtained. When an A/D data register is read using word operand size, the upper byte will automatically be read before the lower byte.

Figure 13-2 shows the data flow when an A/D data register is read. In the example shown, the upper byte of the A/D data register contains H'AA and the lower byte contains H'40. First the H8/500 CPU reads H'AA directly from the upper byte while H'40 is transferred to TEMP in the A/D converter. Next, when the H8/500 CPU reads the lower byte of the A/D data register, it obtains the TEMP contents.

(1) ADDRnH (upper byte) read: ADDRnH [H'AA] → H8/500 CPU [H'AA] (A)
 ADDRnL [H'40] → TEMP [H'40] (B)

(2) ADDRnL (lower byte) read: ADDRnH [H'??] → Not transferred
 ADDRnL [H'??] → Not transferred
 TEMP [H'40] → H8/500 CPU [H'40] (C)

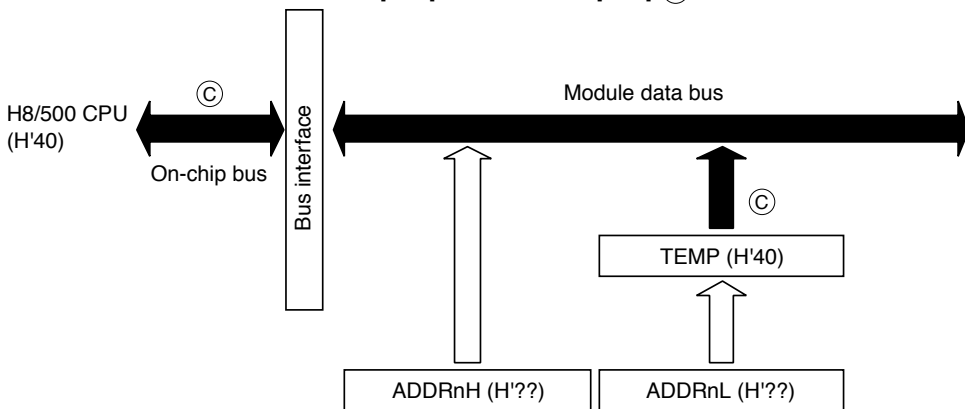

Figure 13-2 A/D Data Register Read Operation (Reading H'AA40)

13.4 Operation

The A/D converter operates by successive approximations with 10-bit resolution. It has two operating modes: single mode and scan mode. In single mode, one selected channel is converted once. In scan mode, one or more selected channels are converted repeatedly until the ADST bit in the A/D control register (ADCR) is cleared to 0.

13.4.1 Single Mode

Single mode can be selected to perform one A/D conversion on one channel. Single mode is selected by clearing bits ADM1 and ADM0 to 00 in the A/D control/status register (ADCSR). A/D conversion then starts when the ADST bit is set to 1 in ADCR. The ADST bit remains set to 1 during A/D conversion and is automatically cleared to 0 when conversion ends. When conversion ends the ADF bit is set to 1 in ADCSR. If the ADIE bit is also set to 1, an ADI interrupt is requested. To clear ADF to 0, first read ADF after ADF has been set to 1, then write 0 in ADF. If the ADI interrupt is served by the data transfer controller (DTC), however, ADF is cleared to 0 automatically.

Figure 13-3 shows a flowchart for selecting analog input channel 1 (AN₁) and performing A/D conversion in single mode. Figure 13-4 is a timing diagram.

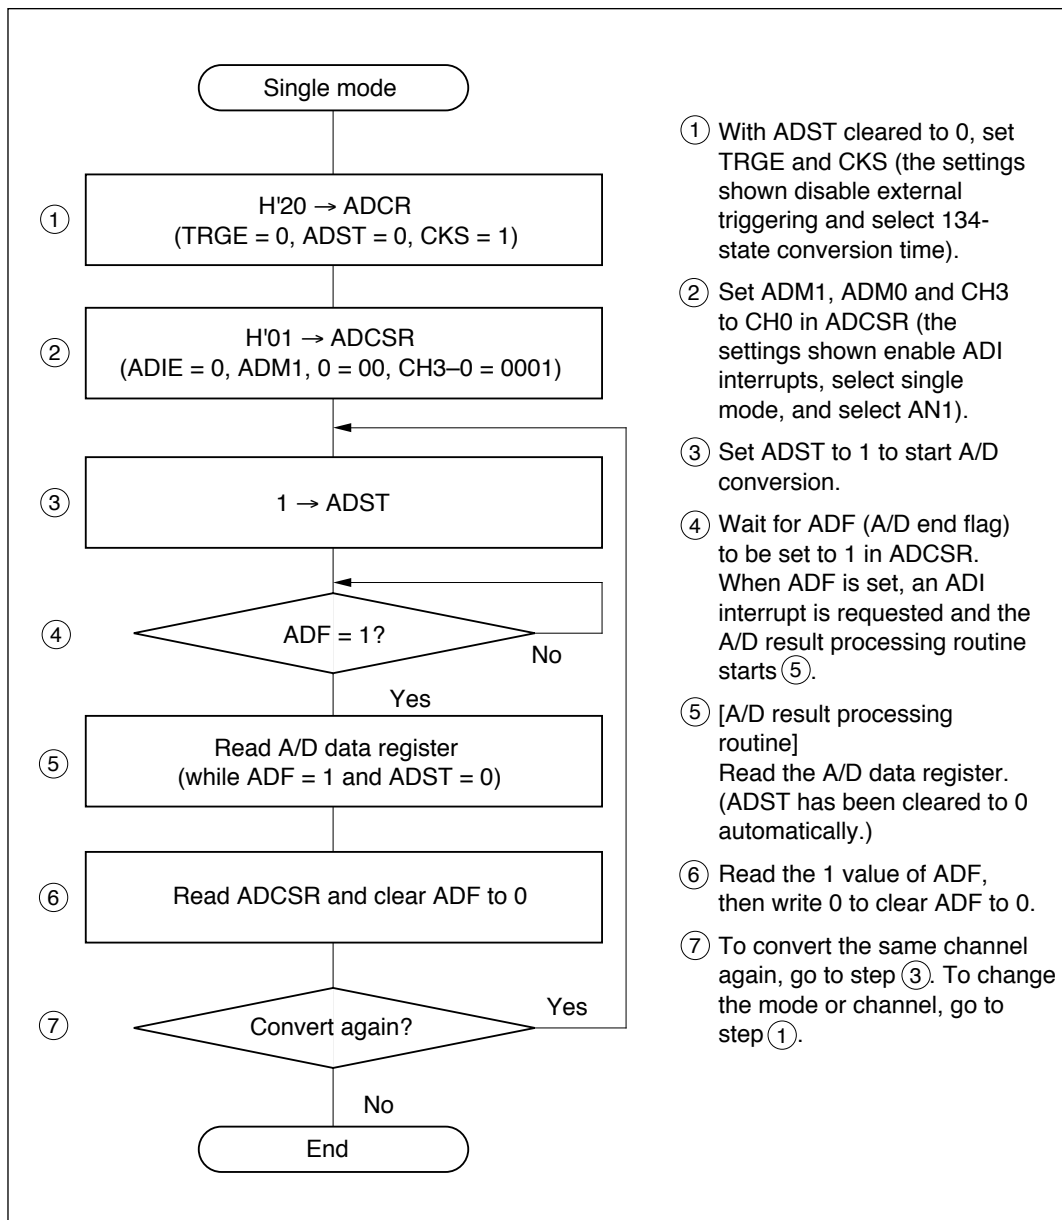

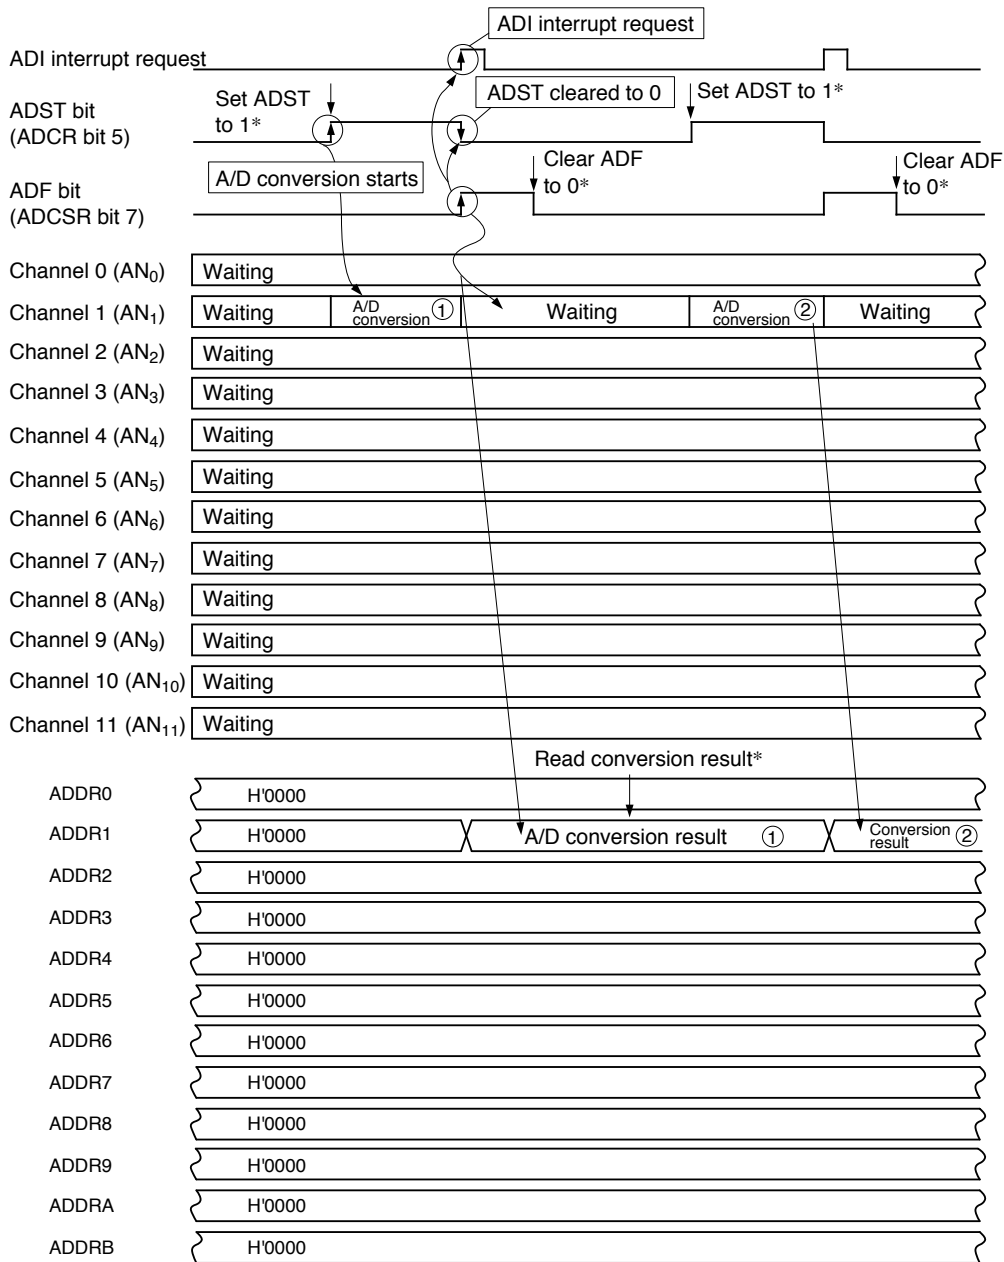

Figure 13-3 Flowchart for Single Mode

Note: * Vertical arrows (↓) indicate instructions executed by software. Boxes indicate operations performed by the A/D converter.

Figure 13-4 Example of A/D Converter Operation (Single Mode, Channel 1 Selected)

13.4.2 Scan Mode

Scan mode can be selected to perform A/D conversion on one or more channels repeatedly (to monitor the channels continuously, for example). Scan mode is selected by setting bits ADM1 and ADM0 in the A/D control/status register (ADCSR) to 01, 10, or 11. The 01 setting selects four-channel scan mode. The 10 setting selects eight-channel scan mode. The 11 setting selects 12-channel scan mode. A/D conversion starts when the ADST bit in ADCR is set to 1.

In scan mode the channels are converted in ascending order of channel number ($AN_0, AN_1, \dots, AN_{11}$). The ADST bit remains set to 1 until software clears it to 0.

When all conversion in one selected analog group is completed, the ADF bit in ADCSR is set to 1, then A/D conversion is performed again. If the ADIE bit in ADCSR is set to 1, then when ADF is set to 1 an ADI interrupt is requested. To clear ADF to 0, first read ADF after it has been set to 1, then write 0 in ADF. If the ADI interrupt is served by the data transfer controller (DTC), however, ADF is cleared to 0 automatically.

Figure 13-5 shows a flowchart for selecting analog input channels 0 and 1 (AN_0 and AN_1) and performing A/D conversion in four-channel scan mode. Figure 13-6 is a timing diagram.

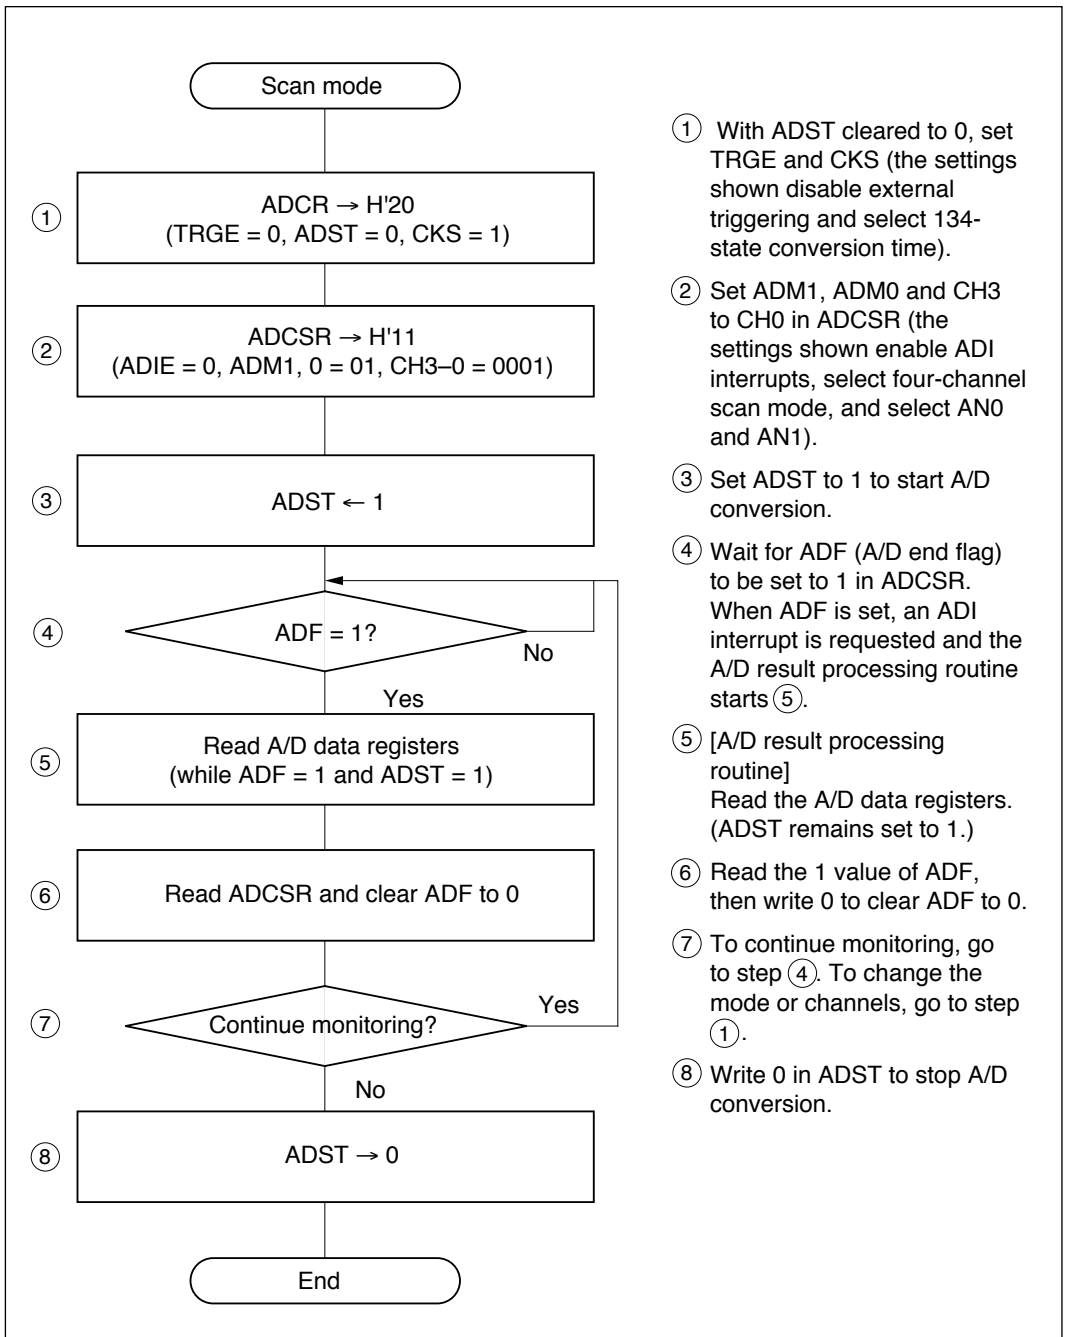

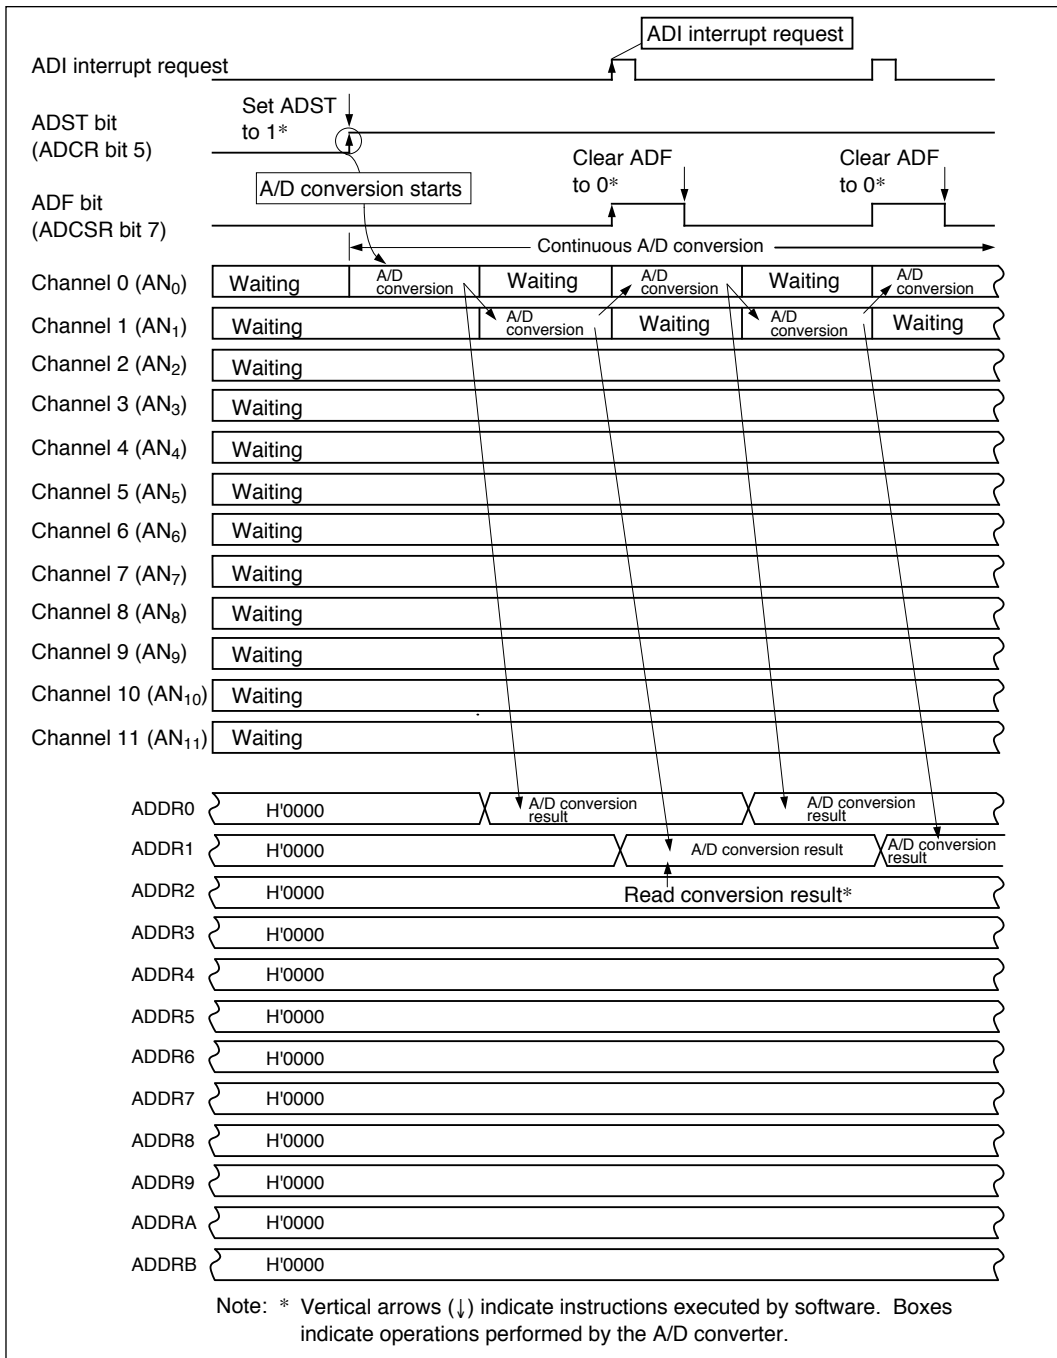

Figure 13-5 Flowchart for Scan Mode

**Figure 13-6 Example of A/D Converter Operation
(Four-Channel Scan Mode, Channels 0 and 1 Selected)**

13.4.3 Analog Input Sampling and A/D Conversion Time

The A/D converter has a built-in sample-and-hold circuit. The A/D converter starts sampling the analog inputs at a time t_D (synchronization delay) after the ADST bit is set to 1 in the A/D control register (ADCR). Figure 13-7 shows the sampling timing.

The A/D conversion time (t_{CONV}) includes t_D and the analog input sampling time (t_{SPL}). The length of t_D varies because it includes time needed to synchronize the A/D converter. The total conversion time therefore varies within the ranges indicated in table 13-4.

In scan mode, the t_{CONV} values given in table 13-4 apply to the first conversion. In the second and subsequent conversions there is no t_D , and t_{CONV} is fixed at 256 states when CKS = 0 or 128 states when CKS = 1.

Table 13-4 A/D Conversion Time (Single Mode)

Item	Symbol	CKS = 0			CKS = 1			Unit
		Min	Typ	Max	Min	Typ	Max	
Synchronization delay	t_D	10	—	17	6	—	9	States
Input sampling time	t_{SPL}	—	80	—	—	40	—	
A/D conversion time	t_{CONV}	259	—	266	131	—	134	

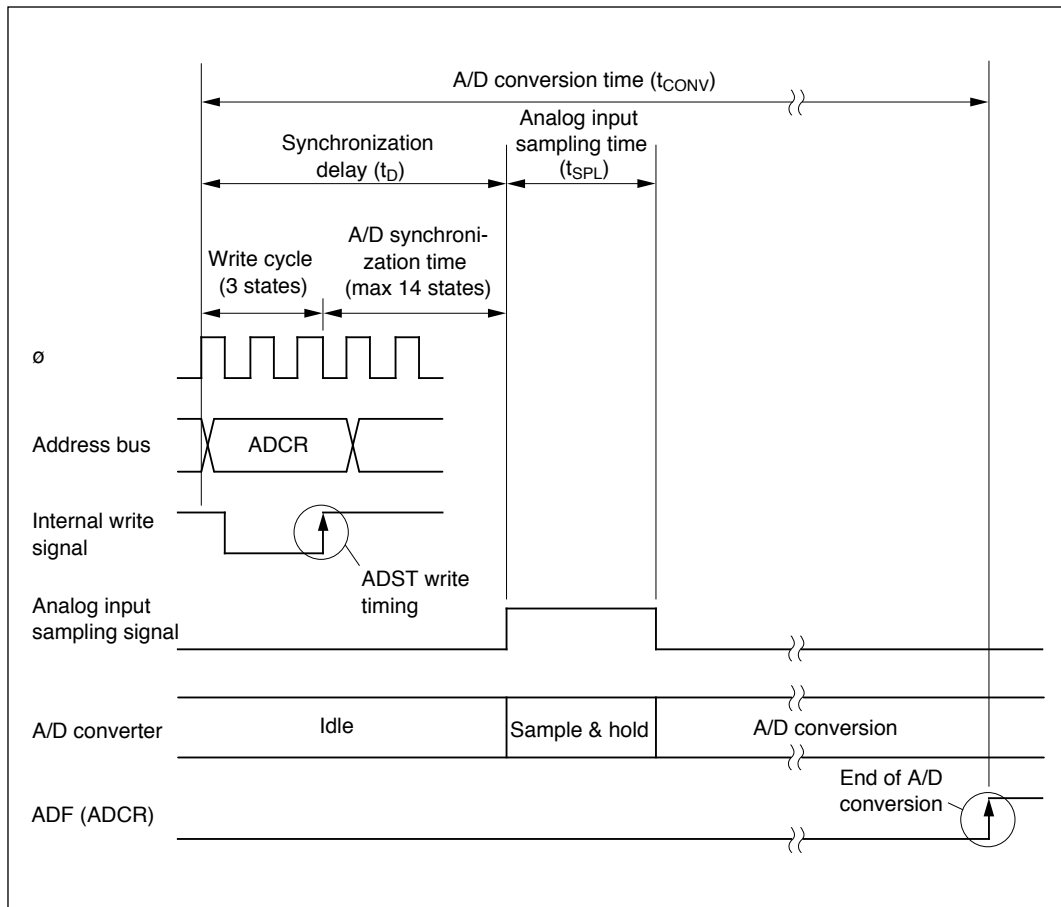

Figure 13-7 A/D Conversion Timing

13.4.4 External Triggering of A/D Conversion

A/D conversion can be started by input of an external trigger signal. External triggering is enabled by setting the TRGE bit to 1 in the A/D control register. When the TRGE bit is set to 1, P7₁ automatically becomes the $\overline{\text{ADTRG}}$ input pin. If a low pulse is input at the $\overline{\text{ADTRG}}$ pin in this state, the A/D converter detects the falling edge of the pulse and sets the ADST bit to 1. Figure 13-8 shows the external trigger input timing.

The ADST bit is set to 1 one state after the A/D converter samples the falling edge of the $\overline{\text{ADTRG}}$ signal. The time from when the ADST bit is set to 1 until A/D conversion begins is the same as when software writes 1 in ADST.

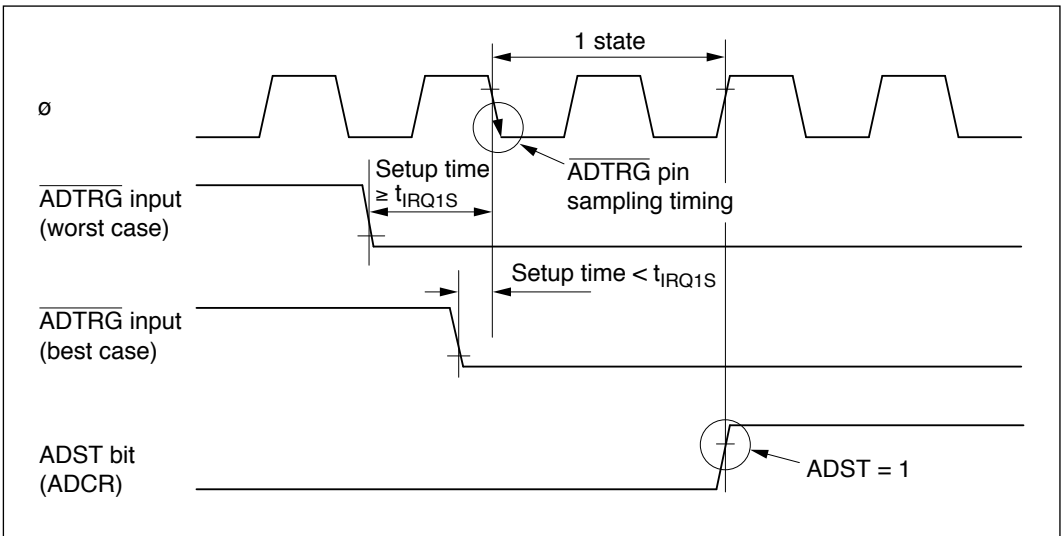

Figure 13-8 External Trigger Input Timing

13.4.5 Starting A/D Conversion by IPU

A/D conversion can be started by a compare match in the H8/538F's integrated-timer pulse unit (IPU). To start A/D conversion by IPU compare match, follow the procedure given next.

1. Set bits DOE21 and DOE20 to 01 in IPU channel 1 timer output enable register A (TOERA).
2. Set the starting time of the A/D converter in IPU channel 1 dedicated register 2 (DR2).
3. Clear the EXTRG bit in the ADTRG register (bit 7 at address H'FEDC) to 0.

After these settings, A/D conversion will start when the IPU channel 1 timer counter value matches DR2. In this case A/D conversion cannot be started by input at the $\overline{\text{ADTRG}}$ pin. When the IPU starts A/D conversion, the timing is the same as if the T1OC₂ pin were externally connected to the $\overline{\text{ADTRG}}$ pin. See the relevant timing diagrams for these pins.

13.5 Interrupts and DTC

The A/D converter can request an A/D end interrupt (ADI) at the end of conversion. ADI is enabled when the ADIE bit is set to 1 in the A/D control/status register (ADCSR), and disabled when ADIE is cleared to 0.

If the ADI bit in the interrupt controller's data transfer enable register A (DTEA) is set to 1, the ADI interrupt is served by the data transfer controller (DTC). When the DTC is started by ADI to perform a data transfer, the ADF bit in ADCSR is automatically cleared to 0. For further details on the DTC, see section 6, "Data Transfer Controller."

13.6 Usage Notes

When using the A/D converter, note the following points:

(1) Analog Input Voltage Range: During A/D conversion, the voltages input to the analog input pins should be in the range $AV_{SS} \leq AN_n \leq V_{REF}$.

(2) Relationships of AV_{CC} and AV_{SS} to V_{CC} and V_{SS} : AV_{CC} , AV_{SS} , V_{CC} , and V_{SS} should be related as follows: $AV_{CC} = V_{CC} \pm 10\%$; $AV_{SS} = V_{SS}$. AV_{CC} and AV_{SS} must not be left open, even if the A/D converter is not used.

(3) V_{REF} Input Range: The reference voltage input at the V_{REF} pin should be in the range $3.5\text{ V} \leq V_{REF} \leq AV_{CC}$.

Failure to observe points (1), (2), and (3) above may degrade chip reliability.

(4) Note on Board Design: In board layout, separate the digital circuits from the analog circuits as much as possible. Particularly avoid layouts in which the signal lines of digital circuits cross or closely approach the signal lines of analog circuits. Induction and other effects may cause the analog circuits to operate incorrectly, or may adversely affect the accuracy of A/D conversion.

The analog input signals (AN_0 to AN_{11}), analog reference voltage (V_{REF}), and analog supply voltage (AV_{CC}) must be separated from digital circuits by the analog ground (AV_{SS}). The analog ground (AV_{SS}) should be connected to a stable digital ground (V_{SS}) at one point on the board.

(5) Note on Noise: To prevent damage from surges and other abnormal voltages at the analog input pins (AN_0 to AN_{11}) and analog reference voltage pin (V_{REF}), connect a protection circuit like the one in figure 13-9 between AV_{CC} and AV_{SS} . The bypass capacitors connected to AV_{CC} and V_{REF} and the filter capacitors connected to AN_0 to AN_{11} must be connected to AV_{SS} . If filter capacitors like those in figure 13-9 are connected, the voltage values input to the analog input pins (AN_0 to AN_{11}) will be smoothed, which may give rise to error. The circuit constants should therefore be selected carefully.

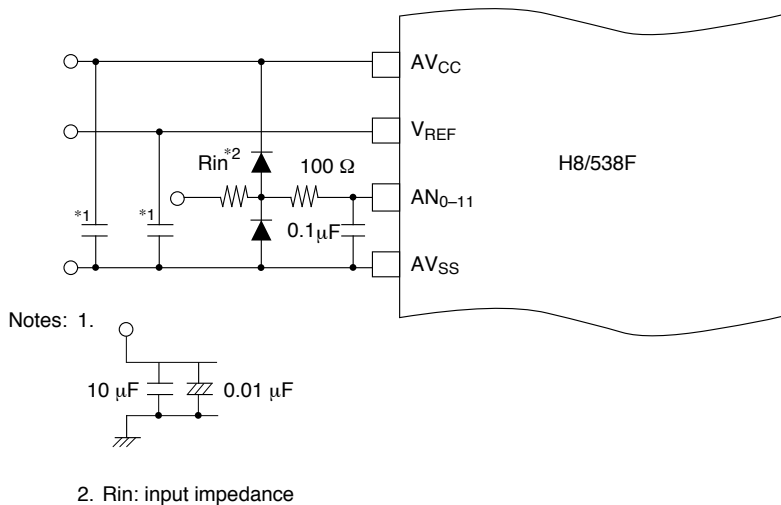

Figure 13-9 Example of Analog Input Protection Circuit

Note: Numeric values are approximate, except in table 13-5.

Figure 13-10 Analog Input Pin Equivalent Circuit

Table 13-5 Analog Input Pin Ratings

Item		Min	Max	Unit
Analog input capacitance		—	20	pF
Allowable signal-source impedance	$8.38 \mu\text{s} \leq \text{conversion time} < 13.4 \mu\text{s}$ $2.7 \text{ V} \leq \text{AV}_{\text{CC}} < 4.5 \text{ V}$	—	5	kΩ
	Other conditions	—	10	kΩ

(6) A/D Conversion Accuracy Definitions: A/D conversion accuracy in the H8/538F is defined as follows:

- Resolution: digital output code length of A/D converter
- Offset error: deviation from ideal A/D conversion characteristic of analog input voltage required to raise digital output from minimum voltage value 0000000000 to 0000000001 (figure 13-12); note that this does not include quantization error
- Full-scale error: deviation from ideal A/D conversion characteristic of analog input voltage required to raise digital output from 1111111110 to 1111111111 (figure 13-12); note that this does not include quantization error
- Quantization error: intrinsic error of the A/D converter; 0.5LSB (figure 13-11)
- Nonlinearity error: deviation from ideal A/D conversion characteristic in range from zero volts to full scale, exclusive of offset error, full-scale error, and quantization error.
- Absolute accuracy: deviation of digital value from analog input value, including offset error, full-scale error, quantization error, and nonlinearity error.

Figure 13-11 A/D Converter Accuracy Definitions (1)

Figure 13-12 A/D Converter Accuracy Definitions (2)

Section 14 Bus Controller

14.1 Overview

The H8/538F has an on-chip bus controller (BSC) that can dynamically alter the bus width and the length of the bus cycle. When a 16-bit bus mode is selected by the inputs at the mode pins, the bus controller can reserve part of the address space as a byte access area accessed via an eight-bit bus, switch another part from a three-state bus cycle to a high-speed two-state bus cycle, and switch the eight-bit-bus area to 16-bit access.

14.1.1 Features

Bus controller features are listed below.

- An eight-bit access area can be defined in the 16-bit bus modes (modes 1, 3, 4, 5*, and 6*)

The eight-bit access area consists of addresses greater than the value set in the byte area top register (ARBT). (This area does not include the address set in ARBT, which is the boundary of the word area.) When an address greater than the ARBT value is accessed, only the upper data bus (D₁₅ to D₈) is valid. The access is performed with eight-bit bus width. The ARBT setting does not change the bus width of the on-chip ROM, on-chip RAM, and on-chip register areas.

Note: * Modes 5 and 6 have a 16-bit bus, but when the chip comes out of reset the ARBT and AR3T settings are ignored: the entire external address space is accessed in three states via an eight-bit bus. Software can enable the ARBT and AR3T settings by altering a value in the bus control register (BCR).

- Two-state access area can be defined

The three-state-access area consists of addresses equal to or greater than the value set in the three-state area top register (AR3T). (The address set in AR3T is included as the boundary of the three-state area.) When addresses less than the AR3T value are accessed, the bus cycle consists of two states. Wait states cannot be inserted in two-state access. The AR3T setting does not change the bus cycle length of the on-chip ROM, on-chip RAM, and on-chip register areas.

- Areas can be defined in steps of 256 bytes in minimum mode, or 4 kbytes in maximum mode.

14.1.2 Block Diagram

Figure 14-1 shows a block diagram of the bus controller.

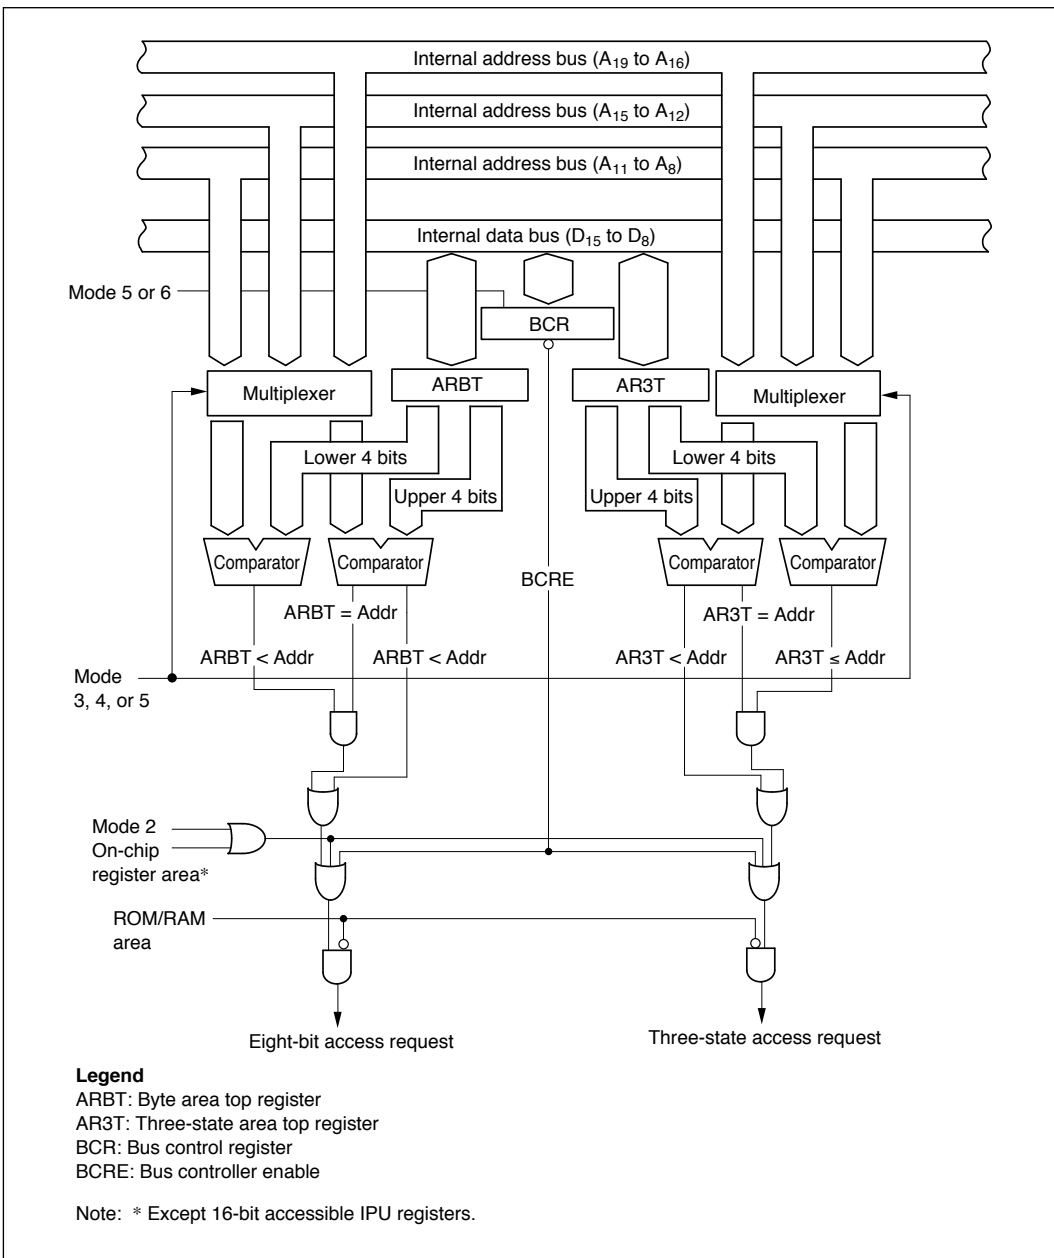

Figure 14-1 Bus Controller Block Diagram

14.1.3 Register Configuration

Table 14-1 summarizes the bus controller’s registers. The bus controller has three 8-bit registers: a byte area top register (ARBT) that designates the boundary of the word area; a three-state area top register (AR3T) that designates the boundary of the three-state-access address space; and a bus control register (BCR) used to switch the bus width in modes 5 and 6. The H8/500 CPU can always read and write ARBT, AR3T, and BCR.

Table 14-1 Bus Controller Registers

Address	Register Name	Abbreviation	R/W	Initial Value
H'FF16	Byte area top register	ARBT	R/W	H'FF
H'FF17	Three-state area top register	AR3T	R/W	H'EE (H'0E)* ¹
H'FEDF	Bus control register	BCR	R/W	H'BF (H'3F)* ²

Notes: 1. H'0E in modes 3, 4, and 5.
2. H'3F in modes 5 and 6.

14.2 Register Descriptions

14.2.1 Byte Area Top Register

The byte area top register (ARBT) specifies the boundary address that separates the area accessed with 16-bit bus width from the area accessed using only the upper eight bits of the 16-bit bus. The address set in ARBT is the word area boundary: the last address accessed with 16-bit bus width.

Bit	7	6	5	4	3	2	1	0
Initial value	1	1	1	1	1	1	1	1
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

The bus controller controls the H8/500 CPU so that external addresses exceeding the ARBT value are accessed with eight-bit bus width.

In expanded maximum mode, the ARBT value is treated as bits A₁₉ to A₁₂ (the upper eight bits) of the word area boundary address. The word area boundary can be set in minimum 4-kbyte steps. In expanded maximum mode, addresses H'00000 to H'00FFF are always a word access area.

In expanded minimum mode, the ARBT value is treated as bits A₁₅ to A₈ (the upper eight bits) of the word area boundary address. The word area boundary can be set in minimum 256-byte steps. In expanded minimum mode, addresses H'0000 to H'00FF are always a word access area.

The ARBT setting applies only to external addresses. It cannot change the bus width of the on-chip ROM or RAM or on-chip register areas. In mode 2 the ARBT setting is ignored: the external address bus has a fixed eight-bit width. In modes 5 and 6 the ARBT setting is ignored until the BCRE bit is set to 1 in the bus control register (BCR).

ARBT is initialized to H'FF by a reset and in hardware standby mode. ARBT is not initialized in software standby mode.

14.2.2 Three-State Area Top Register

The three-state area top register (AR3T) specifies the boundary address that separates the area accessed in two states from the area accessed in three states. The address set in AR3T is the three-state area boundary: the first address accessed in three states.

Bit	7	6	5	4	3	2	1	0
Initial value	1 (0)*	1 (0)*	1 (0)*	0	1	1	1	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Note: * Modes 3 to 5

The bus controller controls the H8/500 CPU so that external addresses equal to or greater than the ARBT value are accessed in three states. Wait states cannot be inserted into the two-state-access area.

In expanded maximum mode, the AR3T value is treated as bits A₁₉ to A₁₂ (the upper eight bits) of the three-state area boundary address. The three-state area boundary can be set in minimum 4-kbyte steps. In expanded maximum mode, addresses H'FF000 to H'FFFFFF are always a three-state-access area.

In expanded minimum mode, the AR3T value is treated as bits A₁₅ to A₈ (the upper eight bits) of the three-state area boundary address. The three-state area boundary can be set in minimum 256-byte steps. In expanded minimum mode, addresses H'FF00 to H'FFFF are always a three-state-access area.

The AR3T setting applies only to external addresses. It cannot change the bus cycle length of the on-chip ROM or RAM or on-chip register areas. In mode 2 the AR3T setting is ignored: the external address space is always a three-state-access area. In modes 5 and 6 the AR3T setting is ignored until the BCRE bit is set to 1 in the bus control register (BCR).

AR3T is initialized to H'EE (modes 1, 2, 6, and 7) or H'0E (modes 3 to 5) by a reset and in hardware standby mode. ARBT is not initialized in software standby mode.

14.2.3 Bus Control Register

The bus control register (BCR) enables or disables the bus controller's bus control functions in modes 5 and 6, and enables or disables on-chip I/O port functions.

Bit	7	6	5	4	3	2	1	0
	BCRE	OP3T	—	P9AE	EXIOP	PCRE	PBCE	P12E
Initial value	0 (1)*	0	1	1	1	1	1	1
R/W	R/W (R)*	R/W	—	R/W	R/W	R/W	R/W	R/W
								<u>Ports 1 and 2 enable</u> Enables and disables reading and writing of ports 1 and 2
							<u>Ports B and C enable</u> Enables and disables reading and writing of ports B and C	
			<u>Reserved bit</u>			<u>Pull-Up transistor control register enable</u> Enables and disables reading and writing of port B and C pull-up transistor control registers		
				<u>Expanded I/O ports</u> Allocates H'0FE9C to H'0FE9F as external addresses				
				<u>Ports 9 and A enable</u> Enables and disables reading and writing of ports 9 and A				
		<u>Zero page three-state</u> Forces three-state access to all addresses in page 0						
	<u>Bus controller enable</u> Enables and disables bus control functions of the bus controller							

Note: * In modes 1, 2, 3, 4, and 7.

When the bus controller enable bit (BCRE) is set to 1, the bus controller controls the bus according to the values in ARBT and AR3T. As an exception, when the zero page three-state bit (0P3T; bit 6) is set to 1, all external addresses in page 0 are placed in the three-state-access area regardless of the AR3T setting.

Bits 4, 2, 1, and 0 enable or disable reading and writing of on-chip I/O ports. If one of these bits is cleared to 0, the corresponding on-chip I/O ports cannot be accessed. The port addresses become part of the external eight-bit three-state-access area instead.

Bit 3 is for I/O port expansion. When this bit is cleared to 0, H'0FE9C to H'0FE9F become part of the external eight-bit three-state-access area.

For precautions on modifying the BCR value, see section 14.4, “Usage Notes.”

(1) Bit 7—Bus Controller Enable (BCRE): Enables or disables bus control functions using the values in ARBT and AR3T in modes 5 and 6.

Bit 7	
BCRE	Description
0	The H8/500 CPU accesses all external addresses in three states using an eight-bit bus* (Initial value in modes 5 and 6) This bit cannot be cleared to 0 in modes 1 to 4 and 7.
1	The H8/500 CPU accesses external addresses according to the ARBT and AR3T settings (Initial value in modes 1 to 4 and 7; cannot be cleared to 0)

Note: * Access is performed using only the upper eight bits (D₁₅ to D₈) of the 16-bit bus.

(2) Bit 6—Zero Page Three-State (0P3T): Selects three-state access for all external addresses in page 0, regardless of the AR3T setting.

Bit 6	
0P3T	Description
0	The H8/500 CPU accesses external addresses according (Initial value) to the ARBT and AR3T settings
1	The H8/500 CPU accesses external addresses according to the ARBT and AR3T settings except in page 0, where three-state access is selected regardless of the AR3T setting*

Note: * In mode 7 there is no external address space, so the 0P3T value has no meaning.

(3) Bit 5—Reserved: Read-only bit, always read as 1. Reserved for future use.

(4) Bit 4—Port 9 and A Enable (P9AE): Enables or disables reading and writing of ports 9 and A, allowing these I/O ports to be reconfigured off-chip.

Bit 4

P9AE	Description
0	On-chip ports 9 and A cannot be written or read The DR and DDR addresses of ports 9 and A (H'0FE90 to H'0FE93) become part of the external eight-bit three-state-access area.*
1	On-chip ports 9 and A can be written and read (Initial value)

Note: * Cannot be cleared to 0 in mode 7.

For details see section 14.3.3, “I/O Port Expansion Function.”

(5) Bit 3—Expanded I/O Ports (EXIOP): Enables or disables expansion of I/O ports, allowing I/O ports to be configured off-chip.

Bit 3

EXIOP	Description
0	External I/O ports can be written and read H'0FE9C to H'0FE9F become part of the external eight-bit three-state-access area.*
1	External I/O ports cannot be written or read (Initial value)

Note: * Cannot be cleared to 0 in mode 7.

For details see section 14.3.3, “I/O Port Expansion Function.”

(6) Bit 2—Pull-Up Transistor Control Register Enable (PCRE): Enables or disables reading and writing of port B and C pull-up transistor control registers (PBPCR and PCPCR).

Bit 2

PCRE	Description
0	Port B and C pull-up transistor control registers (PBPCR and PCPCR) cannot be written or read PBPCR and PCPCR addresses (H'0FE98 to H'0FE9B) become part of the external eight-bit three-state-access area.*
1	Port B and C pull-up transistor control registers (PBPCR and PCPCR) can be written and read (Initial value)

Note: * Cannot be cleared to 0 in mode 7.

For details see section 14.3.3, “I/O Port Expansion Function.”

(7) Bit 1—Port B and C Enable (PBCE): Enables or disables reading and writing of ports B and C, allowing these I/O ports to be reconfigured off-chip.

Bit 1		
PBCE	Description	
0	On-chip ports B and C cannot be written or read The DR and DDR addresses of ports B and C (H'0FE94 to H'0FE97) become part of the external eight-bit three-state-access area.*	
1	On-chip ports B and C can be written and read	(Initial value)

Note: * Cannot be cleared to 0 in mode 7.

For details see section 14.3.3, “I/O Port Expansion Function.”

(8) Bit 0—Port 1 and 2 Enable (P12E): Enables or disables reading and writing of ports 1 and 2, allowing these I/O ports to be reconfigured off-chip.

Bit 0		
P12E	Description	
0	On-chip ports 1 and 2 cannot be written or read The DR and DDR addresses of ports 1 and 2 (H'0FE80 to H'0FE83) become part of the external eight-bit three-state-access area.*	
1	On-chip ports 1 and 2 can be written and read	(Initial value)

Note: * Cannot be cleared to 0 in mode 7.

For details see section 14.3.3, “I/O Port Expansion Function.”

14.3 Operation

14.3.1 Operation after Reset in Each Mode

Figures 14-2 to 14-8 illustrate operation in each mode after a reset.

(1) Mode 1: Has a 16-bit bus. H'0000 to H'EDEF are a 16-bit two-state-access area. H'EE00 to H'FE7F are a 16-bit three-state-access area. When the on-chip RAM is enabled, however, the on-chip RAM area is a 16-bit two-state-access area.

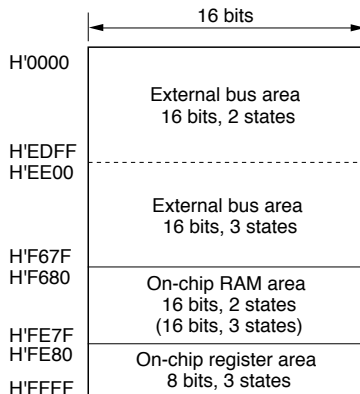

Figure 14-2 Bus Width and Bus Cycle Length after Reset (Mode 1)

(2) Mode 2: Has an eight-bit bus. H'0000 to H'EE7F (on-chip ROM) are a 16-bit two-state-access area. H'EE80 to H'FE7F are an eight-bit three-state-access area. When the on-chip RAM is enabled, however, the on-chip RAM area is a 16-bit two-state-access area.

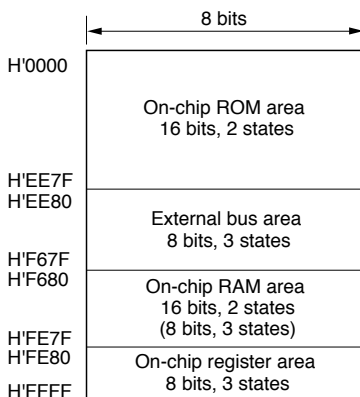

Figure 14-3 Bus Width and Bus Cycle Length after Reset (Mode 2)

(3) Mode 3: Has a 16-bit bus. H'00000 to H'0DFFF are a 16-bit two-state-access area. H'0E000 to H'0FE7F and H'10000 to H'FFFFFF are a 16-bit three-state-access area. When the on-chip RAM is enabled, however, the on-chip RAM area is a 16-bit two-state-access area.

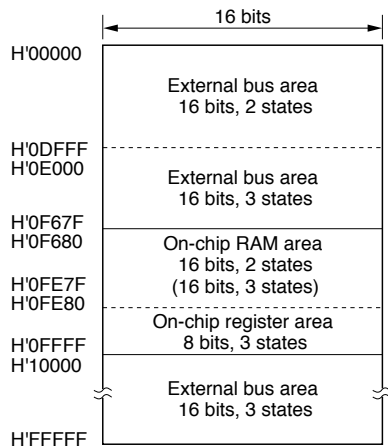

Figure 14-4 Bus Width and Bus Cycle Length after Reset (Mode 3)

(4) Mode 4: Has a 16-bit bus. H'00000 to H'0EE7F (on-chip ROM) are a 16-bit two-state-access area. H'0EE80 to H'0FE7F and H'10000 to H'FFFFFF are a 16-bit three-state-access area. When the on-chip RAM is enabled, however, the on-chip RAM area is a 16-bit two-state-access area.

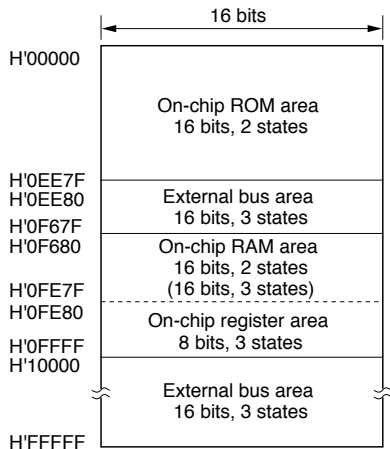

Figure 14-5 Bus Width and Bus Cycle Length after Reset (Mode 4)

(5) Mode 5: Has a 16-bit bus. H'00000 to H'FFFFFF are an eight-bit three-state-access area because BCRE = 0 in the bus control register (BCR). When the on-chip RAM is enabled, however, the on-chip RAM area is a 16-bit two-state-access area.

Figure 14-6 Bus Width and Bus Cycle Length after Reset (Mode 5)

(6) Mode 6: Has a 16-bit bus. H'0000 to H'FE80 are an eight-bit three-state-access area (BCRE = 0 in BCR). When the on-chip RAM is enabled, however, the on-chip RAM area is a 16-bit two-state-access area.

Figure 14-7 Bus Width and Bus Cycle Length after Reset (Mode 6)

(7) Mode 7: Has no external bus. H'0000 to H'EE7F (on-chip ROM) are a 16-bit two-state-access area. When the on-chip RAM is enabled, the on-chip RAM area is a 16-bit two-state-access area.

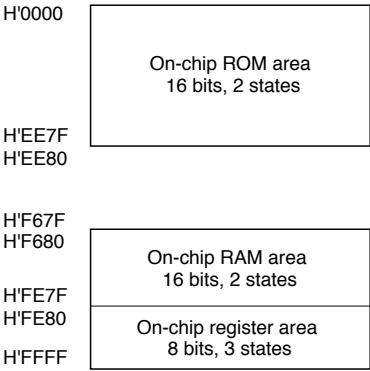

Figure 14-8 Bus Width and Bus Cycle Length after Reset (Mode 7)

14.3.2 Timing of Changes in Bus Areas and Bus Size

Changes in the bus areas and bus size take effect in the next bus cycle after the write cycle to ARBT or AR3T.

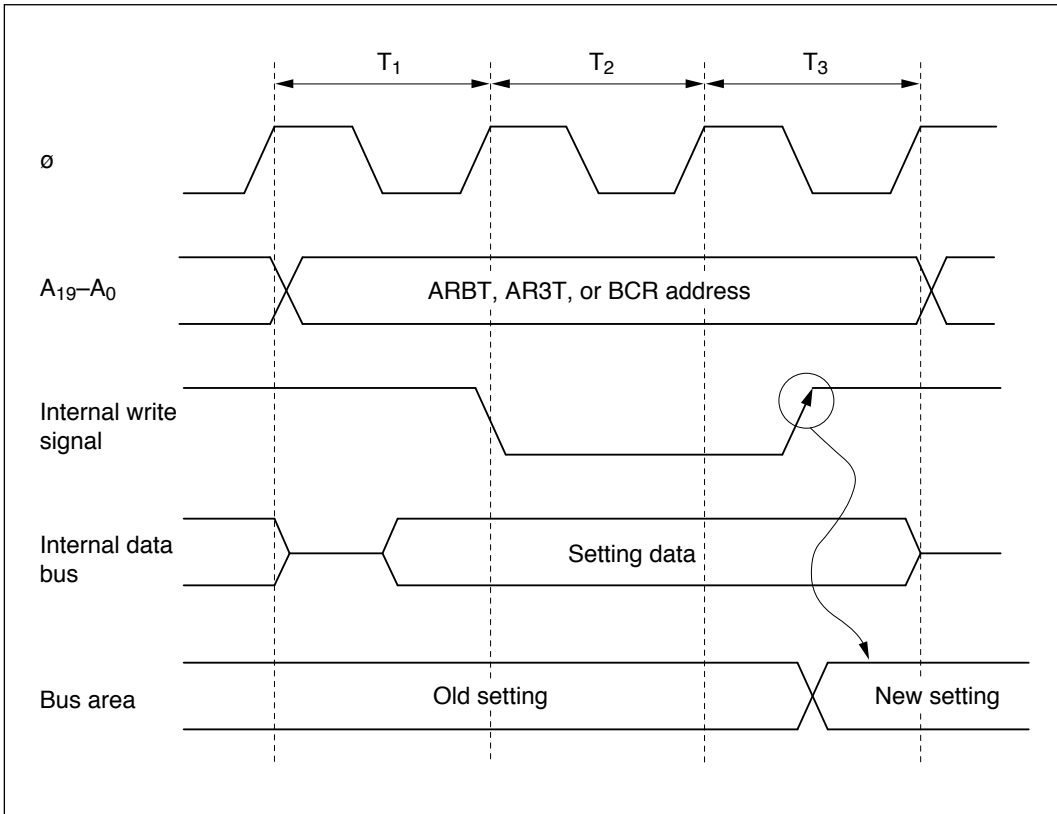

Figure 14-9 Timing of Changes in Bus Controller Settings (Byte Write)

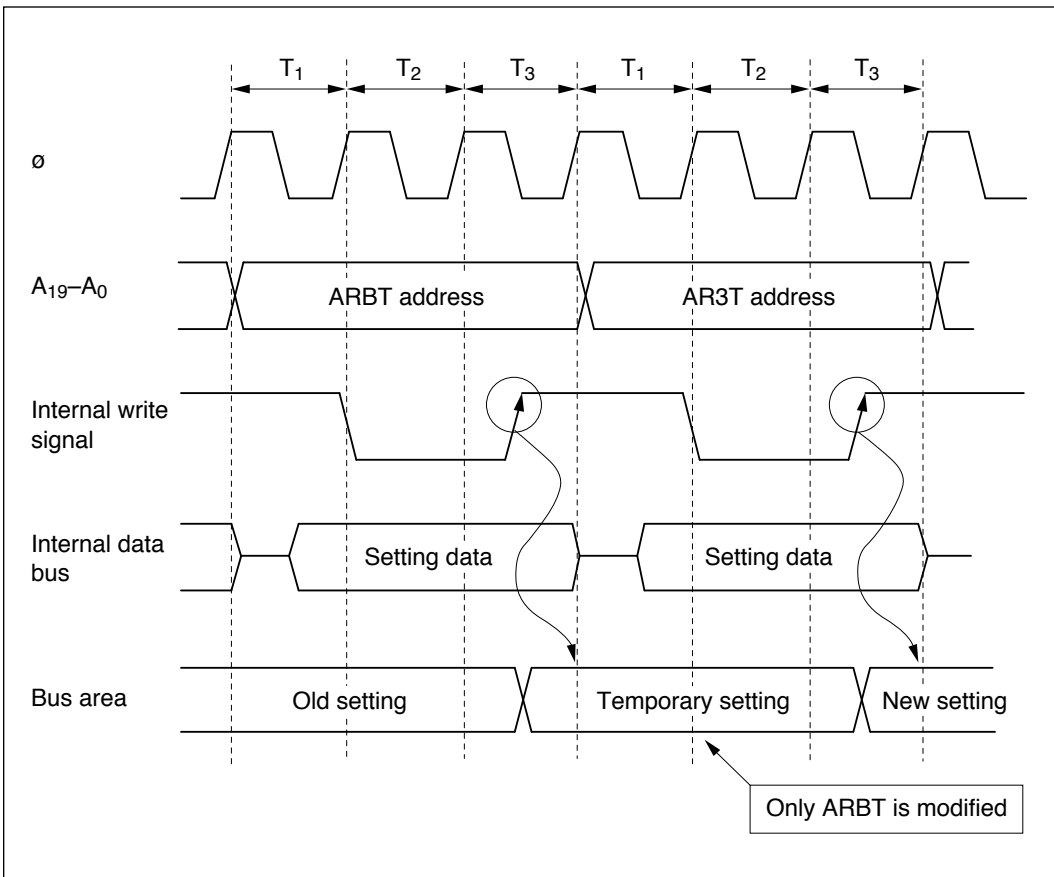

Figure 14-10 Timing of Changes in Bus Controller Settings (Word Write)

14.3.3 I/O Port Expansion Function

Bus control register bits 4 to 0 can be set for I/O port expansion. This function enables ports that become unavailable in expanded modes (modes 1 to 6, ports 1, 2, A, B, and C) to be moved off-chip. Figure 14-11 shows an example of I/O port reconfiguration.

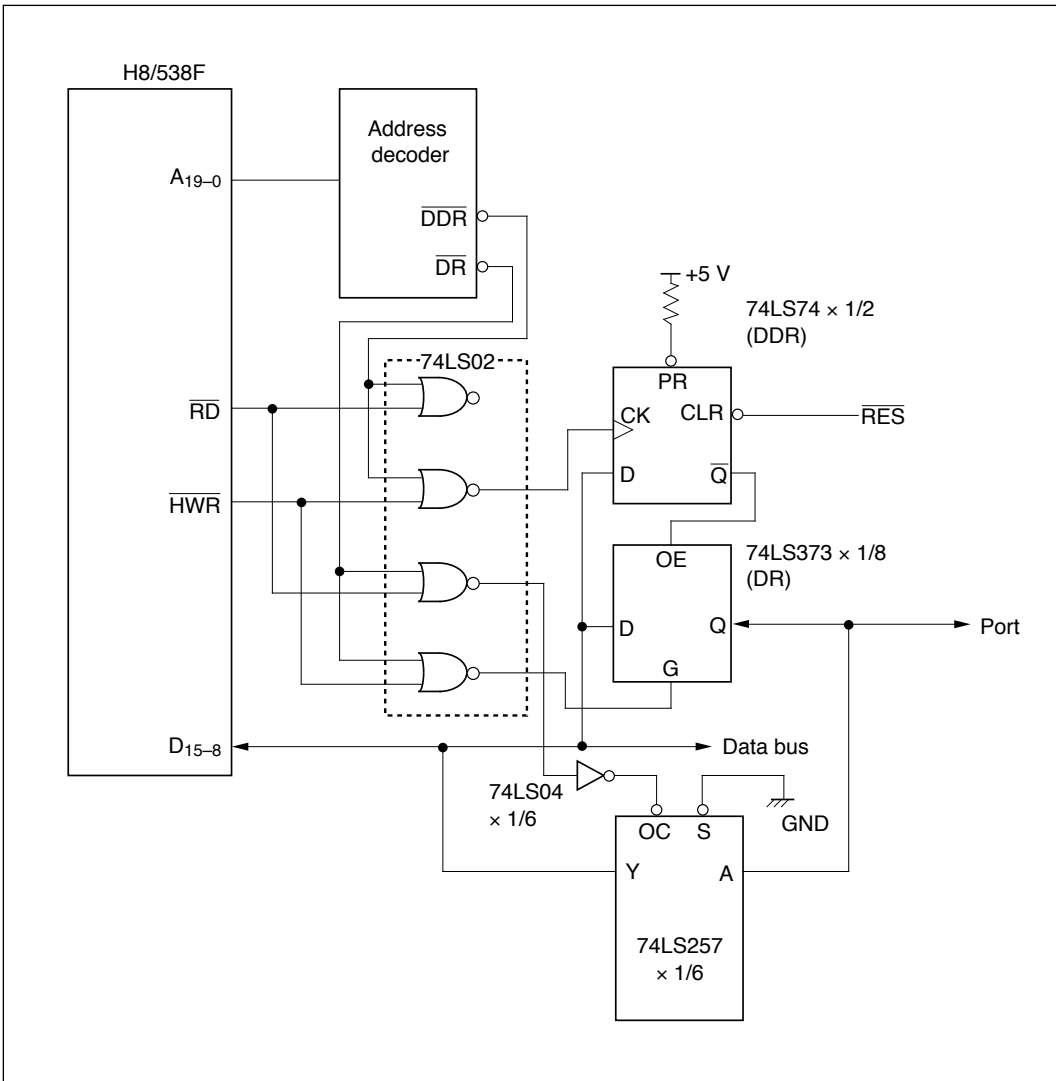

Figure 14-11 Example of I/O Port Reconfiguration (1 Bit)

14.4 Usage Notes

When using the bus controller, note the following points:

(1) Restrictions on AR3T and ARBT Settings: AR3T and ARBT settings should satisfy equation (1).

$$\text{AR3T} \leq \text{ARBT} + 1 \quad \dots (1)$$

No eight-bit, two-state-access area is defined for the H8/538F. If $\text{AR3T} > \text{ARBT} + 1$, eight-bit three-state access is performed.

(2) Possible Partitionings of the Address Space: The address space can be partitioned in eight ways as follows:

1. Two areas: 16 bits, two states; 16 bits, three states
2. Two areas: 16 bits, two states; eight bits, three states
3. Two areas: 16 bits, three states; eight bits, three states
4. Three areas: 16 bits, two states; 16 bits, three states; eight bits, three states
5. One area: eight bits, three states^{*1}
6. Three areas: 16 bits, three states (page 0)^{*2}; 16 bits, two states; 16 bits, three states
7. Three areas: 16 bits, three states (page 0)^{*2}; 16 bits, two states; 8 bits, three states
8. Four areas: 16 bits, three states (page 0)^{*2}; 16 bits, two states; 16 bits, three states; eight bits, three states

Notes: 1. Possible only in modes 5 and 6 when $\text{BCRE} = 0$ in the bus control register (BCR).

2. Set by the 0P3T bit in BCR.

(3) Modification of ARBT, AR3T, and BCR: When ARBT, AR3T, and BCR settings are modified, an invalid bus area may be created temporarily. This may prevent normal program execution. Crashes can be avoided by one of the following methods:

1. Place routines that modify ARBT, AR3T, and BCR in on-chip ROM or RAM.

Perform the modification in an area that is not affected by the ARBT, AR3T, and BCR settings. The modification can be followed by a jump to any area without crashing. (Example 1)

2. Place a branch instruction after the instruction that modifies ARBT, AR3T, or BCR.

After the write to ARBT, AR3T, or BCR,* the instruction fetch from the temporary invalid bus area is cleared by execution of the branch instruction, thus preventing a crash. (Example 2)

Note: * To modify both ARBT and AR3T simultaneously, a word access instruction is recommended.

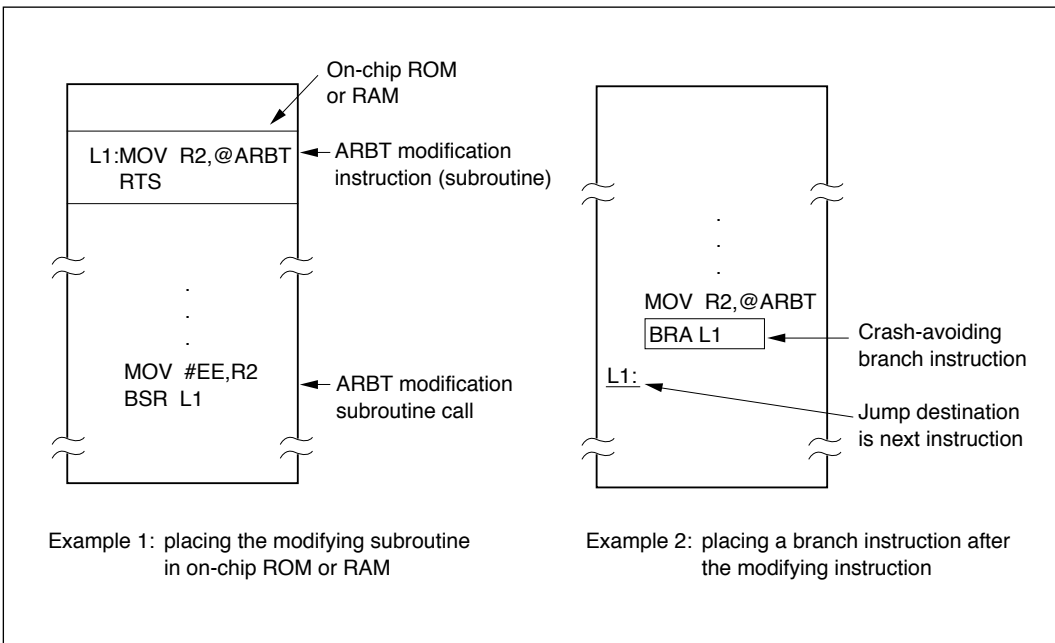

Figure 14-12 Program Structure for Modifying ARBT, AR3T, and BCR

(4) Access Types and Operation of Data Bus and Control Signals: Table 14-2 indicates how the data bus and control signals operate in various types of access.

Table 14-2 (1) Data Bus and Control Signal Operation in Various Types of Access (Mode 2)

No.	Bus Width	Instruction Designations			Data Bus			Control Signals		
		Operand Address	Operand Size	Access Direction	A ₀	D ₁₅ to D ₈	D ₇ to D ₀	\overline{RD}	\overline{HWR}	\overline{LWR}
1	8 bits	Byte area	Byte	Write	0	Output	Not used (port)	H	L	H
2				Write	1	Output		H	L	H
3				Read	0	Input		L	H	H
4				Read	1	Input		L	H	H
5		Word	Word	Write	0	Output		H	L	H
					1	Output		H	L	H
6				Read	0	Input		L	H	H
					1	Input		L	H	H

Notes: 1. How to read the table:

- 1) Bus width: external bus width determined by the operating mode.
- 2) Operand address: area containing the operand address specified in the instruction.
Examples: ARBT > operand address: byte area
ARBT < operand address: word area
- 3) Operand size: size of operand specified in the instruction.
Examples: MOV.B: byte size
MOV.W: word size
- 4) Access direction: as below.
Examples: MOV.B Rn, <EA>: write (CPU → <EA>)
MOV.B <EA>, Rn: read (<EA> → CPU)
2. When a byte area is addressed by an instruction with word operand size, the CPU accesses memory twice, accessing the even byte first, then the odd byte. Instructions that specify word-size operands should always specify an even operand address.

**Table 14-2 (2) Data Bus and Control Signal Operation in Various Types of Access
(Modes 1, 3, and 6)**

No.	Bus Width	Instruction Designations			Data Bus			Control Signals		
		Operand Address	Operand Size	Access Direction	A ₀	D ₁₅ to D ₈	D ₇ to D ₀	$\overline{\text{RD}}$	$\overline{\text{HWR}}$	$\overline{\text{LWR}}$
1	16 bits	Byte area	Byte	Write	0	Output	High impedance	H	L	H
2					1	Output	High impedance	H	L	H
3				Read	0	Input	Don't care	L	H	H
4					1	Input	Don't care	L	H	H
5			Word	Write	0	Output	High impedance	H	L	H
					1	Output	High impedance	H	L	H
6				Read	0	Input	Don't care	L	H	H
					1	Input	Don't care	L	H	H

Notes: 1. How to read the table:

- 1) Bus width: external bus width determined by the operating mode.
- 2) Operand address: area containing the operand address specified in the instruction.
Examples: ARBT > operand address: byte area
ARBT < operand address: word area
- 3) Operand size: size of operand specified in the instruction.
Examples: MOV.B: byte size
MOV.W: word size
- 4) Access direction: as below.
Examples: MOV.B Rn, <EA>: write (CPU → <EA>)
MOV.B <EA>, Rn: read (<EA> → CPU)
2. When a byte area is addressed by an instruction with word operand size, the CPU accesses memory twice, accessing the even byte first, then the odd byte. Instructions that specify word-size operands should always specify an even operand address.

**Table 14-2 (3) Data Bus and Control Signal Operation in Various Types of Access
(Modes 1, 3, and 6)**

No.	Bus Width	Instruction Designations			Data Bus			Control Signals		
		Operand Address	Operand Size	Access Direction	A ₀	D ₁₅ to D ₈	D ₇ to D ₀	$\overline{\text{RD}}$	$\overline{\text{HWR}}$	$\overline{\text{LWR}}$
1	16 bits	Word area	Byte	Write	0	Output	Dummy data	H	L	H
2					1	Dummy data	Output	H	H	L
3				Read	0	Input	Don't care	L	H	H
4					1	Don't care	Input	L	H	H
5			Word	Write	0	Output	Output	H	L	L
					1	—	—	—	—	—
6				Read	0	Input	Input	L	H	H
					1	—	—	—	—	—

Notes: 1. How to read the table:

- 1) Bus width: external bus width determined by the operating mode.
- 2) Operand address: area containing the operand address specified in the instruction.
Examples: ARBT > operand address: byte area
ARBT < operand address: word area
- 3) Operand size: size of operand specified in the instruction.
Examples: MOV.B: byte size
MOV.W: word size
- 4) Access direction: as below.
Examples: MOV.B Rn, <EA>: write (CPU → <EA>)
MOV.B <EA>, Rn: read (<EA> → CPU)
2. Instructions that specify word-size operands should always specify an even operand address.

Figures 14-13 and 14-14 show examples of usage of the bus controller in mode 4.

1. $AR3T \leq ARBT + 1$

Figure 14-13 Example of Use of Bus Controller (Mode 4)

2. $AR3T > ARBT + 1$

Figure 14-14 Example of Use of Bus Controller (Mode 4)

Section 15 RAM

15.1 Overview

The H8/538F has 2 kbytes of on-chip static RAM. The RAM is connected to the H8/500 CPU by a 16-bit data bus. The H8/500 CPU accesses both byte data and word data in two states, making the RAM suitable for rapid data transfer and high-speed computation.

The on-chip RAM is assigned to addresses H'F680 to H'FE7F. The RAM control register (RAMCR) enables this area to be switched between on-chip RAM and external memory.

15.1.1 Block Diagram

Figure 15-1 shows a block diagram of the on-chip RAM.

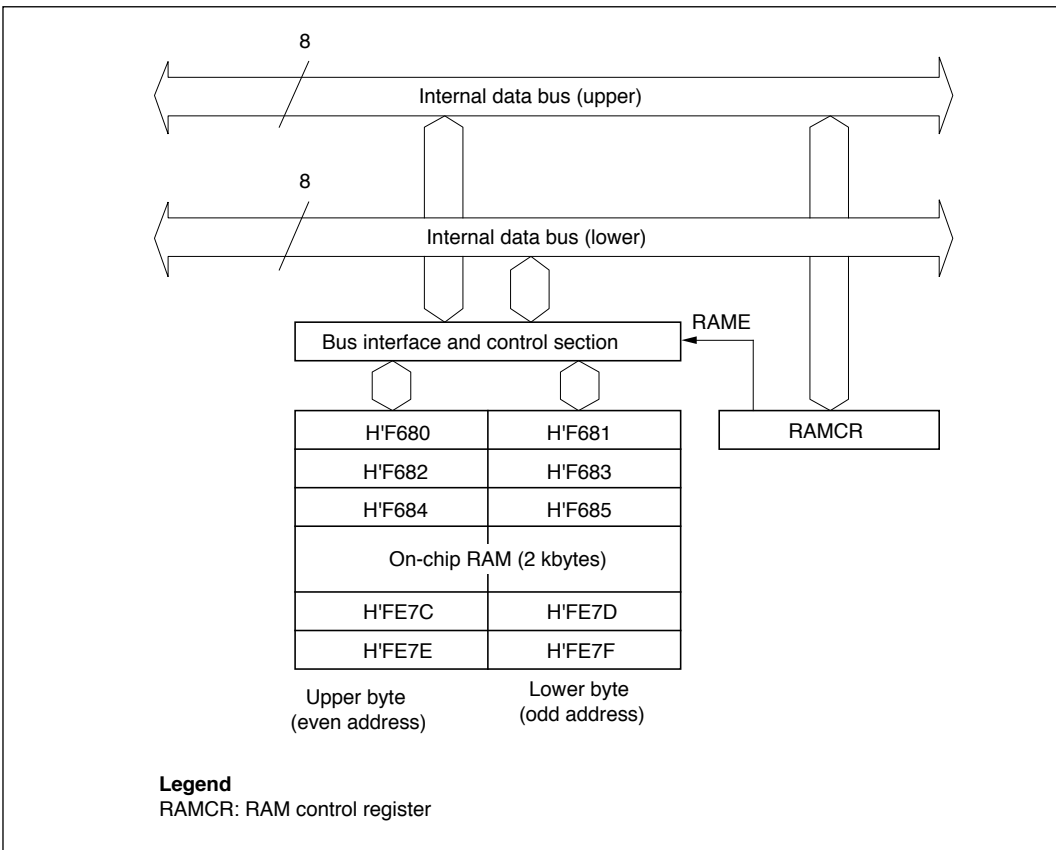

Figure 15-1 RAM Block Diagram

15.1.2 Register Configuration

The RAM is controlled by the RAM control register (RAMCR). Table 15-1 gives the address and initial value of RAMCR.

Table 15-1 RAM Control Register

Address	Register Name	Abbreviation	R/W	Initial Value
H'FF15	RAM control register	RAMCR	R/W	Undetermined

15.2 RAM Control Register

The RAM control register (RAMCR) enables or disables access to the on-chip RAM. It can also indicate flash-memory errors and reassign flash-memory addresses to RAM. For details on the flash-memory functions, see section 16.2.4, “RAM Control Register.”

Bit	7	6	5	4	3	2	1	0
	RAME	—	—	FLER	RAMS	RAM2	RAM1	RAM0
Initial value	1	*	1	0	0	0	0	0
R/W	R/W	—	—	R	R/W	R/W	R/W	R/W

Reserved bits

RAM Enable bit

Enables and disables access to on-chip RAM

Note: * Bit 6 is reserved for chip testing and has an undetermined value when written or read.

(1) **Bit 7—RAM Enable (RAME):** Enables or disables access to on-chip RAM.

Bit 7	
RAME	Description
0	On-chip RAM cannot be accessed
1	On-chip RAM can be accessed (Initial value)

The RAME bit is initialized on the rising edge of the reset signal. It is not initialized in software standby mode. In modes 1 to 6, when the RAME bit is cleared to 0 to disable access to on-chip RAM, addresses H'F680 to H'FE7F become an external memory area.

(2) **Bits 6 to 5—Reserved:** Bit 6 is reserved by the system for chip testing and has an undetermined value when written or read. Bits 5 are read-only bits that always read 1 and cannot be modified.

15.3 Operation

15.3.1 Expanded Modes (Modes 1 to 6)

In the expanded modes, when the RAME bit is set to 1, accesses to addresses H'F680 to H'FE7F are directed to the on-chip RAM. When the RAME bit is cleared to 0, accesses to addresses H'F680 to H'FE7F are directed to off-chip memory.

15.3.2 Single-Chip Mode (Mode 7)

In single-chip mode, when the RAME bit is set to 1, accesses to addresses H'F680 to H'FE7F are directed to the on-chip RAM. When the RAME bit is cleared to 0, any type of access to addresses H'F680 to H'FE7F (instruction fetch or data read/write) causes an address error. For the exception handling when an address error occurs, see section 4, “Exception Handling.”

Section 16 Flash Memory

16.1 Overview

16.1.1 Flash Memory Overview

Table 16-1 illustrates the principle of operation of the H8/538F's on-chip flash memory.

Like EPROM, flash memory is programmed by applying a high gate-to-drain voltage that draws hot electrons generated in the vicinity of the drain into a floating gate. The threshold voltage of a programmed memory cell is therefore higher than that of an erased cell. Cells are erased by grounding the gate and applying a high voltage to the source, causing the electrons stored in the floating gate to tunnel out. After erasure, the threshold voltage drops. A memory cell is read like an EPROM cell, by driving the gate to the high level and detecting the drain current, which depends on the threshold voltage. Erasing must be done carefully, because if a memory cell is overerased, its threshold voltage may become negative, causing the cell to operate incorrectly.

Section 16.4.6 shows an optimal erase control flowchart and sample program.

Table 16-1 Principle of Memory Cell Operation

	Program	Erase	Read
Memory cell			
Memory array			

16.1.2 Mode Programming and Flash Memory Address Space

As its on-chip ROM, the H8/538F has 60 kbytes of flash memory. The flash memory is connected to the CPU by a 16-bit data bus. The CPU accesses both byte data and word data in two states.

The flash memory is assigned to addresses H'0000 to H'EE7F on the memory map. The mode pins enable either on-chip flash memory or external memory to be selected for this area. Table 16-2 summarizes the mode pin settings and usage of the flash memory area.

Table 16-2 Mode Pin Settings and Flash Memory Area

Mode	Mode Pin Setting			Flash Memory Area Usage
	MD ₂	MD ₁	MD ₀	
Mode 0	0	0	0	Illegal setting
Mode 1	0	0	1	External memory area
Mode 2	0	1	0	On-chip flash memory area
Mode 3	0	1	1	External memory area
Mode 4	1	0	0	On-chip flash memory area
Mode 5	1	0	1	External memory area
Mode 6	1	1	0	External memory area
Mode 7	1	1	1	On-chip flash memory area

16.1.3 Features

Features of the flash memory are listed below.

- Five flash memory operating modes

The flash memory has five operating modes: program mode, program-verify mode, erase mode, erase-verify mode, and prewrite-verify mode.

- Block erase designation

Blocks to be erased in the flash memory address space can be selected by bit settings. The address space includes a large-block area (seven 8-kbyte blocks) and a small-block area (eight blocks with sizes from 128 bytes to 1 kbyte).

- Program and erase time

Programming one byte of flash memory typically takes 50 μ s. Erasing typically takes 1 s.

- Erase-program cycles

Flash memory contents can be erased and reprogrammed up to 100 times.

- On-board programming modes

These modes can be used to program, erase, and verify flash memory contents. There are two modes: boot mode, and user programming mode.

- Automatic bit-rate alignment

In boot-mode data transfer, the H8/538F aligns its bit rate automatically to the host bit rate (maximum 9600 bps).

- Flash memory emulation by RAM

Part of the RAM area can be overlapped onto flash memory, to emulate flash memory updates in real time.

- PROM mode

As an alternative to on-board programming, the flash memory can be programmed and erased in PROM mode, using a general-purpose PROM programmer.

16.1.4 Block Diagram

Figure 16-1 shows a block diagram of the flash memory.

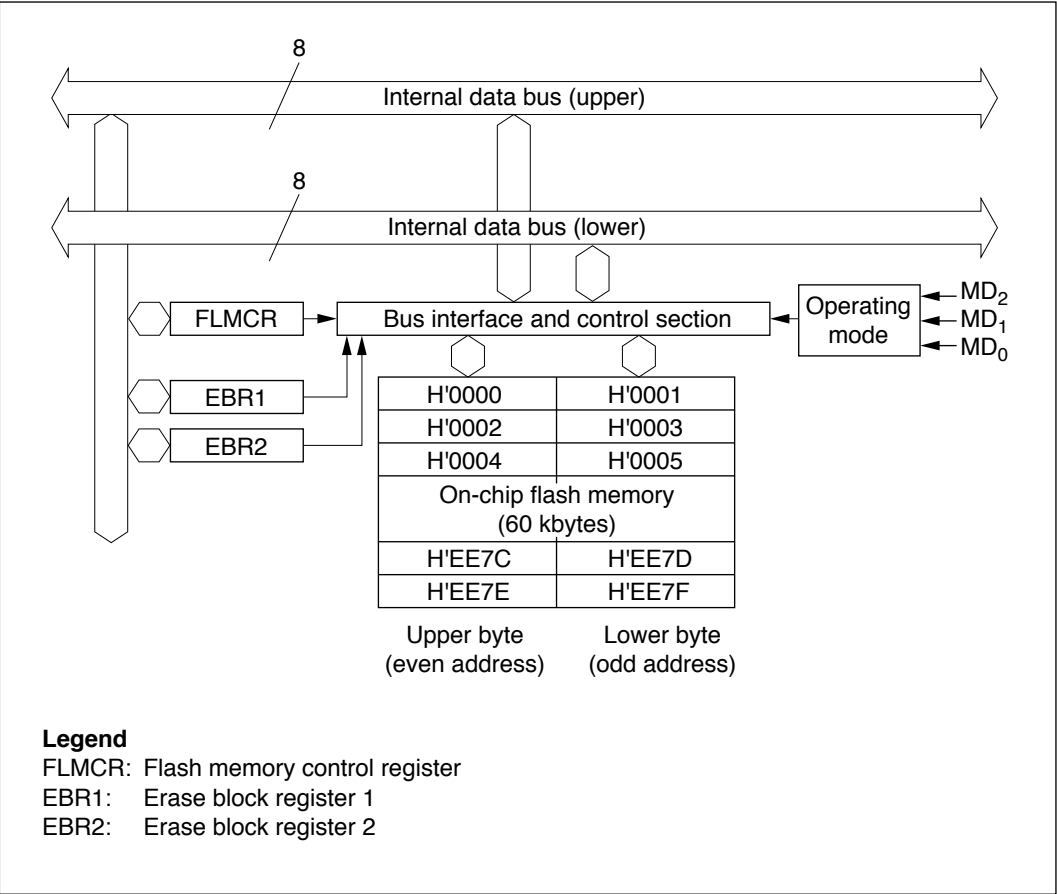

Figure 16-1 Flash Memory Block Diagram

16.1.5 Input/Output Pins

Flash memory is controlled by the pins listed in table 16-3.

Table 16-3 Flash Memory Pins

Pin Name	Abbreviation	Input/Output	Function
Programming power	V _{PP}	Power supply	Apply 12.0 V
Mode 2	MD ₂	Input	H8/538F operating mode programming
Mode 1	MD ₁	Input	H8/538F operating mode programming
Mode 0	MD ₀	Input	H8/538F operating mode programming
Transmit data	TXD ₁	Output	Serial transmit data output
Receive data	RXD ₁	Input	Serial receive data input

The transmit data and receive data pins are used in boot mode.

16.1.6 Register Configuration

The flash memory is controlled by the registers listed in table 16-4.

Table 16-4 Flash Memory Registers

Name	Abbreviation	R/W	Initial Value	Address
Flash memory control register	FLMCR	R/W*3	H'00*3	H'FEE0
Erase block register 1	EBR1	R/W*3	H'00*3	H'FEE2
Erase block register 2	EBR2	R/W*3	H'00*3	H'FEE3
RAM control register*1	RAMCR	R/W	Undetermined*2	H'FF15

- Notes:
1. The RAM control register enables or disables access to the on-chip RAM, but it is also used in this chapter for RAM reassignment in on-board programming mode, and to indicate flash-memory errors.
 2. The initial value is H'F0 or H'B0. Bit 6 is reserved for chip testing, and has an undetermined value when written or read.
 3. The initial value is H'00 in modes 2, 4, and 7 (on-chip flash memory enabled). In modes 1, 3, 5, and 6 (on-chip flash memory disabled), this register cannot be modified and always reads H'FF.

16.2 Register Descriptions

16.2.1 Flash Memory Control Register

The flash memory control register (FLMCR) is an eight-bit register that controls the flash memory operating modes. Transitions to program mode, erase mode, program-verify mode, and erase-verify mode are made by setting bits in this register. FLMCR is initialized to H'00 by a reset, in the standby modes, and when 12 V is not applied to V_{PP} . When 12 V is applied to V_{PP} , a reset or entry to a standby mode initializes FLMCR to H'80. The FLMCR bit structure is shown next.

Bit	7	6	5	4	3	2	1	0
	V_{PP}	—	—	—	EV	PV	E	P
Initial value*	0	0	0	0	0	0	0	0
R/W	R	—	—	—	R/W*	R/W*	R/W*	R/W*

— Programming power
Status flag indicating that
12 V is applied to V_{PP}

— Reserved bits

— Erase-verify mode
Designates transition to
or exit from erase-verify
mode

— Program-verify mode
Designates transition to
or exit from program-verify
mode

— Erase mode
Designates transition
to or exit from erase
mode

— Program mode
Designates
transition to
or exit from
program mode

Note: * The initial value is H'00 in modes 2, 4, and 7 (on-chip flash memory enabled). In modes 1, 3, 5, and 6 (on-chip flash memory disabled), this register cannot be modified and always reads H'FF.

(1) **Bit 7—Programming Power (V_{PP}):** This status flag indicates that 12 V is applied to the V_{PP} pin. For further information, see note 5 in section 16.7, “Flash Memory Programming and Erasing Precautions.”

Bit 7

V_{PP}	Description	
0	Cleared when 12 V is not applied to V_{PP}	(Initial value)
1	Set when 12 V is applied to V_{PP}	

(2) **Bits 6 to 4—Reserved:** Read-only bits, always read as 0.

(3) **Bit 3—Erase-Verify Mode (EV):*** Selects transition to or exit from erase-verify mode.

Bit 3

EV	Description	
0	Exit from erase-verify mode	(Initial value)
1	Transition to erase-verify mode	

(4) **Bit 2—Erase-Verify Mode (PV):*** Selects transition to or exit from program-verify mode.

Bit 2

PV	Description	
0	Exit from program-verify mode	(Initial value)
1	Transition to program-verify mode	

(5) **Bit 1—Erase Mode (E):*** Selects transition to or exit from erase mode.

Bit 1

E	Description	
0	Exit from erase mode	(Initial value)
1	Transition to erase mode	

(6) **Bit 0—Program Mode (P):*** Selects transition to or exit from program mode.

Bit 0

P	Description	
0	Exit from program mode	(Initial value)
1	Transition to program mode	

Note: * Do not set two or more of these bits simultaneously.

16.2.2 Erase Block Register 1

Erase block register 1 (EBR1) is an eight-bit register that designates large flash-memory blocks for erasure. EBR1 is initialized to H'00 by a reset, in the standby modes, and when 12 V is not applied to V_{pp}. When a bit in EBR1 is set to 1, the corresponding block is selected and can be erased. Figure 16-2 shows a block map.

Bit	7	6	5	4	3	2	1	0
	—	LB6	LB5	LB4	LB3	LB2	LB1	LB0
Initial value*	0	0	0	0	0	0	0	0
R/W	—	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*

Note: * The initial value is H'00 in modes 2, 4, and 7 (on-chip flash memory enabled). In modes 1, 3, 5, and 6 (on-chip flash memory disabled), this register cannot be modified and always reads H'FF.

- (1) **Bit 7—Reserved:** Read-only bit, always read as 0.
- (2) **Bits 6 to 0—Large Block 6 to 0 (LB6 to LB0):** These bits select large blocks (LB6 to LB0) to be erased.

Bits 6 to 0

LB6 to LB0	Description
0	Block LB6 to LB0 is not selected (Initial value)
1	Block LB6 to LB0 is selected

16.2.3 Erase Block Register 2

Erase block register 2 (EBR2) is an eight-bit register that designates small flash-memory blocks for erasure. EBR2 is initialized to H'00 by a reset, in the standby modes, and when 12 V is not applied to V_{PP}. When a bit in EBR2 is set to 1, the corresponding block is selected and can be erased. Figure 16-2 shows a block map.

Bit	7	6	5	4	3	2	1	0
	SB7	SB6	SB5	SB4	SB3	SB2	SB1	SB0
Initial value*	0	0	0	0	0	0	0	0
R/W	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*

Note: * The initial value is H'00 in modes 2, 4, and 7 (on-chip flash memory enabled). In modes 1, 3, 5, and 6 (on-chip flash memory disabled), this register cannot be modified and always reads H'FF.

(1) Bits 7 to 0—Small Block 7 to 0 (SB7 to SB0): These bits select small blocks (SB7 to SB0) to be erased.

Bits 7 to 0

SB7 to SB0	Description
0	Block SB7 to SB0 is not selected (Initial value)
1	Block SB7 to SB0 is selected

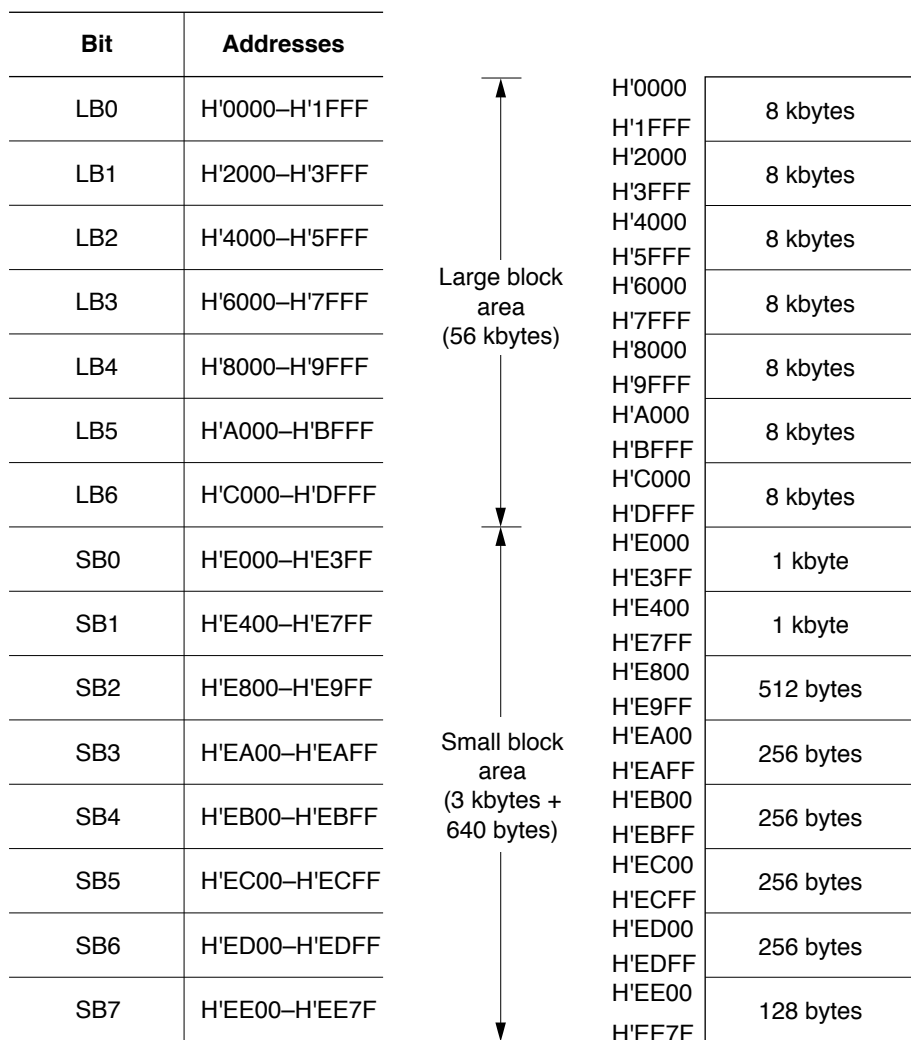

Figure 16-2 Erase Block Map

16.2.4 RAM Control Register

The RAM control register (RAMCR) enables flash-memory updates to be emulated in RAM, and indicates flash memory errors. Bit 7 of RAMCR also enables or disables access to the on-chip RAM. For details, see section 16.5, “Flash Memory Emulation by RAM.”

Bit	7	6	5	4	3	2	1	0
	RAME	—	—	FLER	RAMS	RAM2	RAM1	RAM0
Initial value	1	*	1	0	0	0	0	0
R/W	R/W	—	—	R	R/W	R/W	R/W	R/W

RAM2/1/0
Specifies a flash-memory area to be overlapped by RAM

RAM select
Enables or disables overlapping of RAM onto a small-block area of flash memory

Flash memory error
Status flag indicating that an error was detected during programming or erasing

Reserved bits

RAM enable
Enables or disables access to on-chip RAM

Note: * Bit 6 is used for chip testing and has undetermined values when written or read.

(1) Bit 7—RAM Enable (RAME): When bit 7 is cleared to 0, access to on-chip RAM is disabled and the settings of bits 3 to 0 are ignored. For details see section 15.2, “RAM Control Register.”

(2) Bits 6 and 5—Reserved: Bit 6 is reserved by the system for chip testing and has an undetermined value when written or read. Bit 5 is a read-only bit that always reads 1 and cannot be modified.

(3) Bit 4—Flash Memory Error (FLER): Indicates that an error occurred while flash memory was being programmed or erased. When bit 4 is set, flash memory is placed in an error-protect mode.*1

Bit 4		
FLER	Description	
0	Flash memory is not write/erase-protected (is not in error protect mode*1) (Clearing conditions) Reset or hardware standby mode	(Initial value)
1	Indicates that an error occurred while flash memory was being programmed or erased, and error protection*1 is in effect (Setting conditions) 1. Flash memory was read*2 while being programmed or erased (including vector or instruction fetch, but not including reading of a RAM area overlapped onto flash memory). 2. A hardware exception-handling sequence (other than a reset, trace exception, invalid instruction, trap instruction, or zero-divide exception) was executed just before programming or erasing. 3. The SLEEP instruction (for transition to sleep mode or software standby mode) was executed during programming or erasing.	

Notes: 1. For details, see section 16.4.8, “Protect Modes.”
2. The read data has undetermined values.

(4) Bit 3—RAM Select (RAMS): Is used with bits 2 to 0 to reassign an area to RAM (see table 16-5). When bit 3 is set, all flash-memory blocks are protected from programming and erasing, regardless of the values of bits 2 to 0. This state is referred to as emulation protection.*1 In this state the flash memory will not enter program mode or erase mode even if the P or E bit is set in the flash memory control register (FLMCR). Only transitions to verify modes are possible. Bit 3 must be cleared to 0 to enable flash memory to be actually programmed or erased.

In on-board programming mode this bit is initially 0 but can be modified by writing 1. In other modes this bit cannot be modified and always reads 0. It is initialized by a reset and in hardware standby mode. It is not initialized in software standby mode. It is also initialized when 12 V is not applied to Vpp.*2

(5) Bits 2 to 0—RAM2 to RAM0: These bits are used with bit 3 to reassign an area to RAM (see table 16-5). In on-board programming mode these bits are initially 0 but can be modified by writing 1. In other modes these bits cannot be modified and always read 0. They are initialized by a reset and in hardware standby mode. They are not initialized in software standby mode. They are also initialized when 12 V is not applied to Vpp.*2

- Notes: 1. For emulation protection, see section 16.4.8, “Protect Modes.”
2. It is possible to write to RAMS only when the V_{pp} flag in the flash memory control register (FLMCR) is set. For further information about the setting and clearing of the V_{pp} flag, see note 5 in section 16.7, “Flash Memory Programming and Erasing Precautions.”

Table 16-5 RAM Area* Reassignment

RAM Area*	Bit 3	Bit 2	Bit 1	Bit 0	Reassignment	Program/Erase Protection
	RAMS	RAM2	RAM1	RAM0		
(H'F680 to H'F6FF)	0	0/1	0/1	0/1	Disabled	Disabled
H'EC00 to H'EC7F	1	0	0	0	Enabled	Enabled
H'EC80 to H'ECFF	1	0	0	1	Enabled	Enabled
H'ED00 to H'ED7F	1	0	1	0	Enabled	Enabled
H'ED80 to H'EDFF	1	0	1	1	Enabled	Enabled
H'EE00 to H'EE7F	1	1	0	0	Enabled	Enabled
(H'F680 to H'F6FF)	1	1	0	1	Disabled	Enabled
	1	1	1	0		
	1	1	1	1		

Note: * Flash-memory addresses overlapped by RAM.

16.3 On-Board Programming Modes

When an on-board programming mode is selected, the on-chip flash memory can be programmed, erased, and verified. There are two on-board programming modes: boot mode, and user program mode. These modes are selected by inputs at the mode pins (MD₂ to MD₀) and V_{PP} pin. Table 16-6 indicates how to select the on-board programming modes. For information about turning V_{PP} on and off, see note 5 in section 16.7, “Flash Memory Programming and Erasing Precautions.”

Table 16-6 On-Board Programming Mode Selection

Mode Selections		V _{PP}	MD ₂	MD ₁	MD ₀	Notes
Boot mode	Mode 2	12 V	12 V	1	0	0: V _{IL} 1: V _{IH}
	Mode 4		12 V	0	0	
	Mode 7		12 V	1	1	
User program mode	Mode 2		0	1	0	
	Mode 4		1	0	0	
	Mode 7		1	1	1	

16.3.1 Boot Mode

To use boot mode, a user program for programming and erasing the flash memory must be provided in advance on the host machine (which may be a personal computer). Serial communication interface channel 1 is used in asynchronous mode (see figure 16-3). If the H8/538F is placed in boot mode, after it comes out of reset, a built-in boot program is activated. This program starts by measuring the low period of data transmitted from the host and setting the bit rate register (BRR) accordingly. The H8/538F’s built-in serial communication interface (SCI) can then be used to download the user program from the host machine. The user program is stored in on-chip RAM.

After the program has been stored, execution branches to address H'F900 in the on-chip RAM, and the program stored on RAM is executed to program and erase the flash memory. Figure 16-4 shows the boot-mode execution procedure.

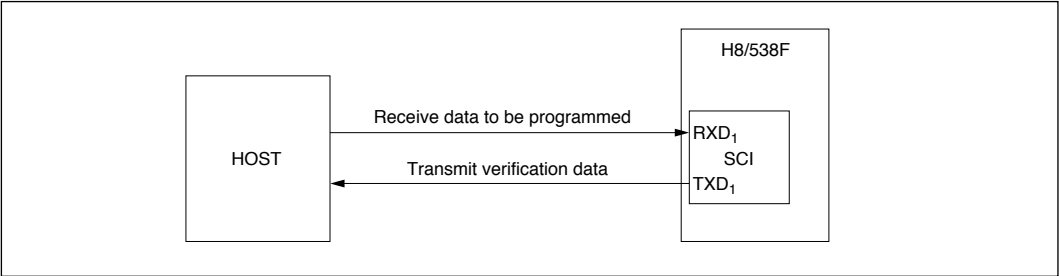

Figure 16-3 Boot-Mode System Configuration

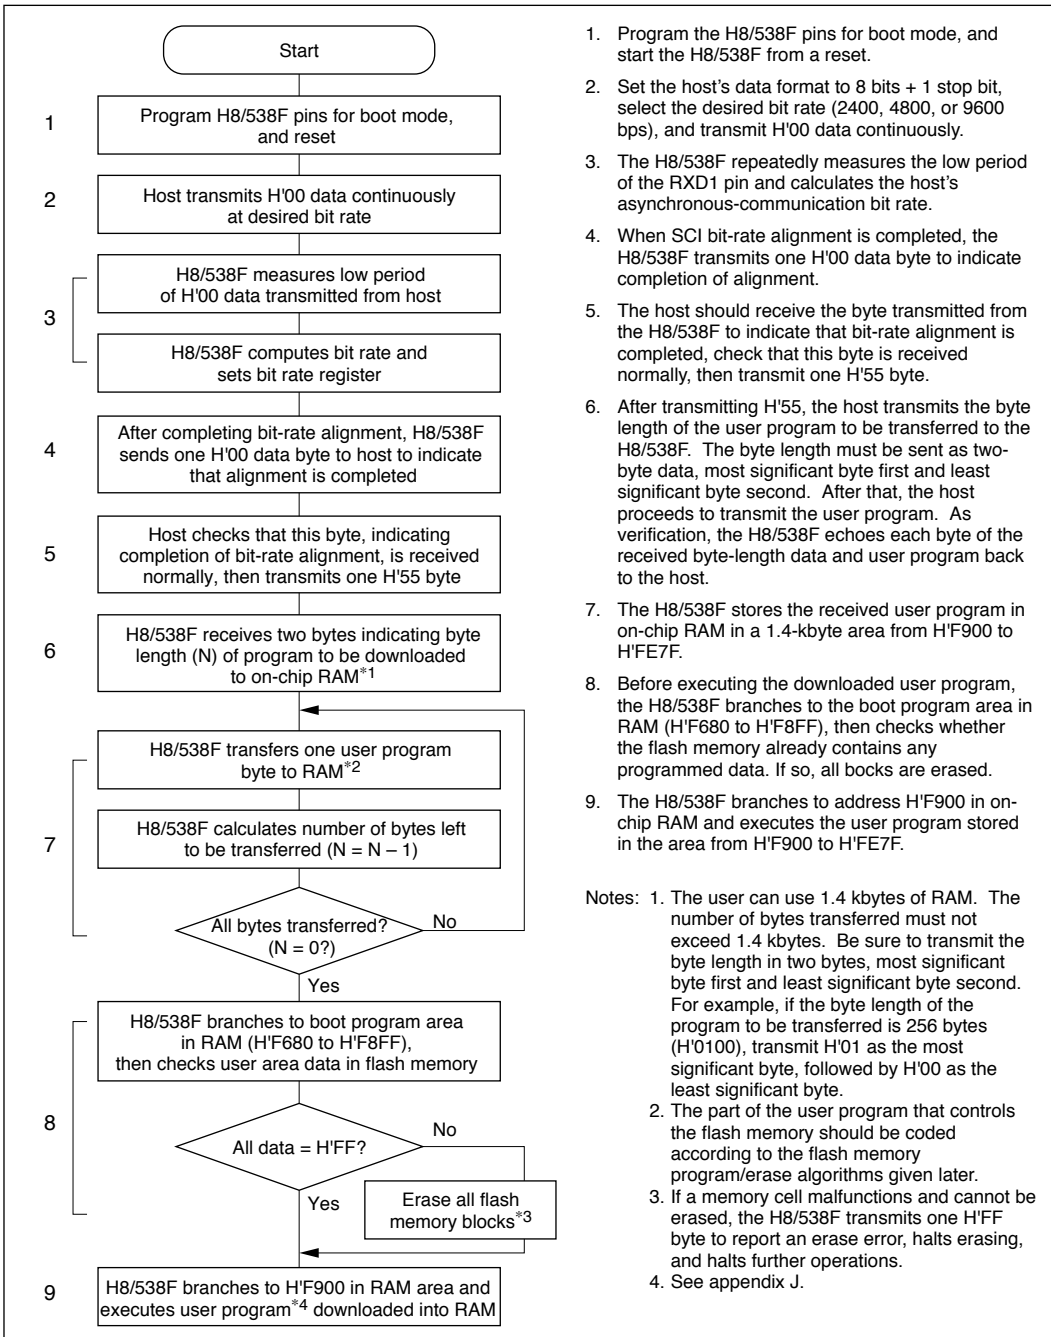

Figure 16-4 Boot Mode Flowchart

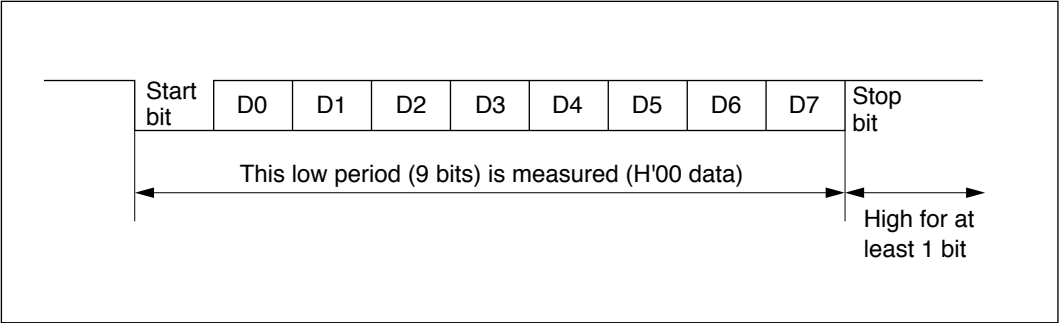

Figure 16-5 Measurement of Low Period in Data Transmitted from Host

When started in boot mode, the H8/538F measures the low period in asynchronous SCI data transmitted from the host (figure 16-5). The data format is eight data bits, one stop bit, and no parity bit. From the measured low period (nine bits), the H8/538F computes the host’s bit rate. After aligning its own bit rate, the H8/538F sends the host one byte of H'00 data to indicate that bit-rate alignment is completed. The host should check that this alignment-completed indication is received normally, then transmit one H'55 byte. If the host does not receive a normal alignment-completed indication, the H8/538F should be reset, then restarted in boot mode to measure the low period again. There may be some alignment error between the host’s and H8/538F’s bit rates, depending on the host’s bit rate and the H8/538F’s system clock frequency. To have the SCI operate normally, set the host’s bit rate to a value from 2400 to 9600 bps. Table 16-7 lists typical host bit rates and indicates the clock-frequency ranges over which the H8/538F can align its bit rate automatically. Boot mode should be used within these frequency ranges.

Table 16-7 System Clock Frequencies Permitting Automatic Bit-Rate Alignment by H8/538F

Host Bit Rate	System Clock Frequencies Permitting Automatic Bit-Rate Alignment by H8/538F
9600 bps	8 MHz to 16 MHz
4800 bps	4 MHz to 16 MHz
2400 bps	2 MHz to 16 MHz

RAM Area Allocation in Boot Mode: In boot mode, the 640 bytes from H'F680 to H'F8FF are reserved for use by the boot program. The user program is transferred into the area from H'F900 to H'FE7F (approximately 1.4 kbytes). The boot program area is used during the transition to execution of the user program transferred into RAM.

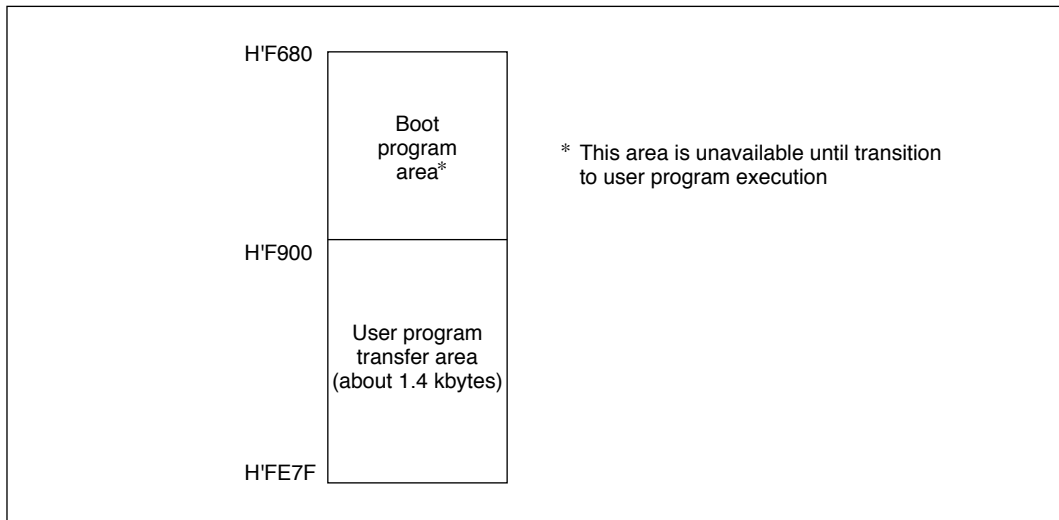

Figure 16-6 RAM Areas in Boot Mode

Notes on Use of Boot Mode

1. When the H8/538F comes out of reset in boot mode, it measures the low period of the input at the SCI's RXD₁ pin. The reset should end with RXD₁ high. After the reset ends, it takes about 100 states for the H8/538F to get ready to measure the low period of the RXD₁ input.
2. In boot mode, if any data has been programmed into the flash memory (if all data are not H'FF), all flash memory blocks are erased. Boot mode is for use when user program mode is unavailable, e.g. the first time on-board programming is performed, or if the update program activated in user program mode is accidentally erased.
3. Interrupts cannot be used while the flash memory is being programmed or erased.
4. The RXD₁ and TXD₁ lines should be pulled up on-board.
5. Before branching to the user program (at address H'F900 in the RAM area), the H8/538F terminates transmit and receive operations by the on-chip SCI (by clearing the RE and TE bits to 0 in channel 1), but the auto-aligned bit rate remains set in bit rate register BRR1. The transmit data pin (TXD₁) is in the high output state (in port 7, the P7₂DDR and P7₂DR bits are set to 1).

When the branch to the user program occurs, the contents of general registers in the CPU are undetermined. After the branch, the user program should begin by initializing general registers, especially the stack pointer (SP), which is used implicitly in subroutine calls and at other times. The stack pointer must be set to provide a stack area for use by the user program. The other on-chip registers do not have specific initialization requirements.

16.3.2 User Program Mode

When set to user program mode, the H8/538F can erase and program its flash memory by executing a user program. On-board updates of the on-chip flash memory can be carried out by providing on-board circuits for supplying V_{PP} and data, and storing an update program in part of the program area.

To select user program mode, select a mode that enables the on-chip ROM (mode 2, 4, or 7) and apply 12 V to the V_{PP} pin. In this mode, the on-chip peripheral modules operate as they normally would in mode 2, 4, or 7, except for the flash memory. A watchdog timer overflow, however, cannot output a reset signal while 12 V is applied to V_{PP} . The watchdog timer's reset output enable bit (RSTOE) should not be set to 1.

The flash memory cannot be read while being erased, so the update program must either be stored in external memory, or transferred temporarily to the RAM area and executed in RAM.

User Program Mode Execution Procedure: Figure 16-7 shows the procedure for user program mode execution in RAM.

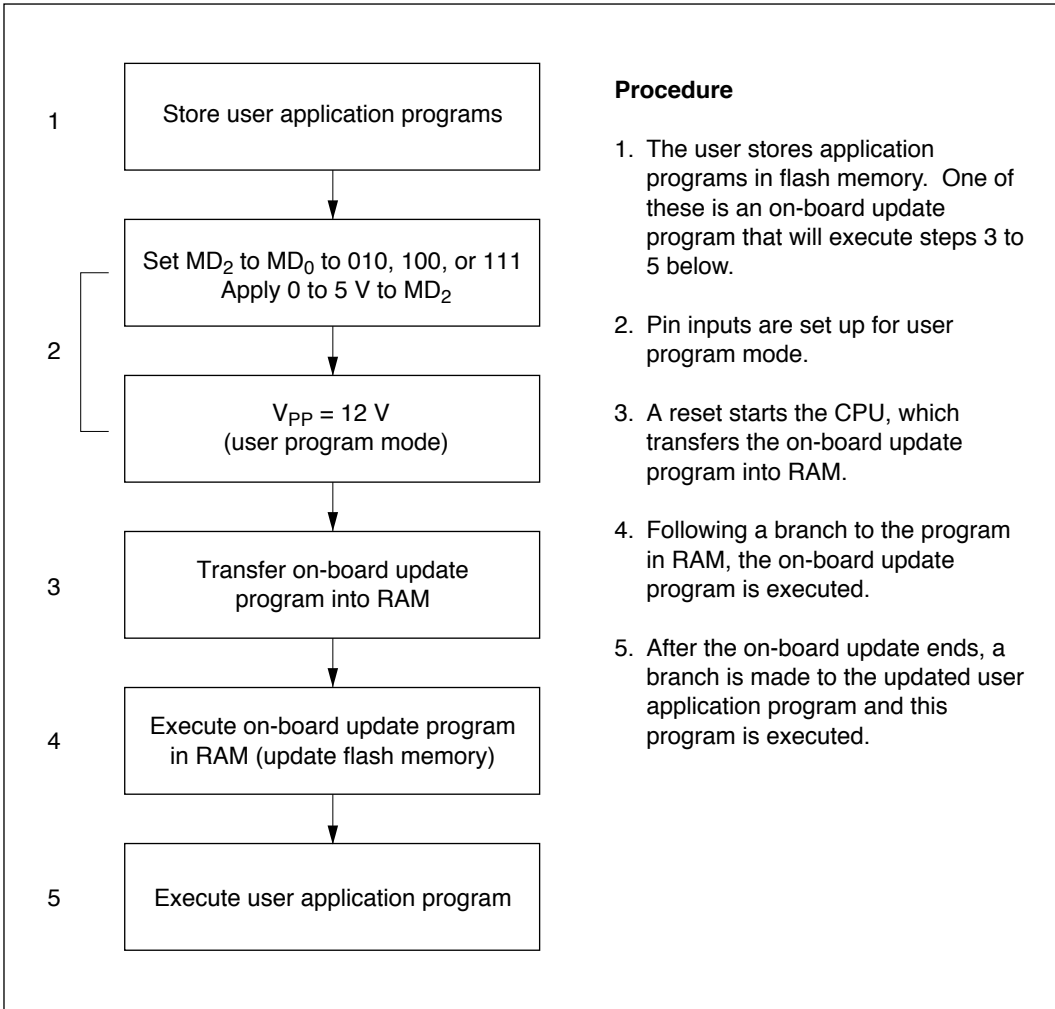

Figure 16-7 User Program Mode Operation (Example)

Note: Do not apply 12 V to the V_{PP} pin during normal operation. To prevent microcontroller errors caused by accidental programming or erasing, apply 12 V to V_{PP} only when the flash memory is programmed or erased, or when flash memory is emulated by RAM. While 12 V is applied, the watchdog timer should be running and enabled to halt runaway program execution, so that program runaway will not lead to overprogramming or overerasing. For further information about turning V_{PP} on and off, see note 5 in section 16.7, “Flash Memory Programming and Erasing Precautions.”

16.4 Programming and Erasing Flash Memory

The H8/538F's on-chip flash memory is programmed and erased by software, using the CPU. The flash memory can operate in program mode, erase mode, program-verify mode, erase-verify mode, or prewrite-verify mode. Transitions to these modes can be made by setting the P, E, PV, and EV bits in the flash memory control register (FLMCR).

The flash memory cannot be read while being programmed or erased. The program that controls the programming and erasing of the flash memory must be stored and executed in on-chip RAM or in external memory. A description of each mode is given below, with recommended flowcharts and sample programs for programming and erasing. Section 16.7, "Flash Memory Programming and Erasing Precautions," gives further notes on programming and erasing.

16.4.1 Program Mode

To write data into the flash memory, follow the programming algorithm shown in figure 16-8. This programming algorithm can write data without subjecting the device to voltage stress or impairing the reliability of programmed data.

To program data, first write the data to the address to be programmed, as in writing to RAM. The flash memory latches the address and data in an address latch and data latch. Next set the P bit in FLMCR, selecting program mode. The programming duration is the time during which the P bit is set. A software timer should be used to provide a programming duration of about 10 to 20 μ s. Programming for too long a time, due to program runaway for example, can cause device damage. Before selecting program mode, set up the watchdog timer so as to prevent overprogramming.

16.4.2 Program-Verify Mode

In program-verify mode, after data has been programmed in program mode, the data is read to check that it has been programmed correctly.

After the programming time has elapsed, exit programming mode (clear the P bit to 0) and select program-verify mode (set the PV bit to 1). In program-verify mode, a program-verify voltage is applied to the memory cells at the latched address. If the flash memory is read in this state, the data at the latched address will be read. After selecting program-verify mode, wait 2 μ s before reading, then compare the programmed data with the verify data. If they agree, exit program-verify mode and program the next address. If they do not agree, select program mode again and repeat the same program and program-verify sequence. Do not repeat the program and program-verify sequence more than 20* times for the same bit.

Note: * When a bit is programmed repeatedly, set a loop counter so that the total programming time will not exceed 200 μ s.

16.4.3 Programming Flowchart and Sample Program

Flowchart for Programming One Byte

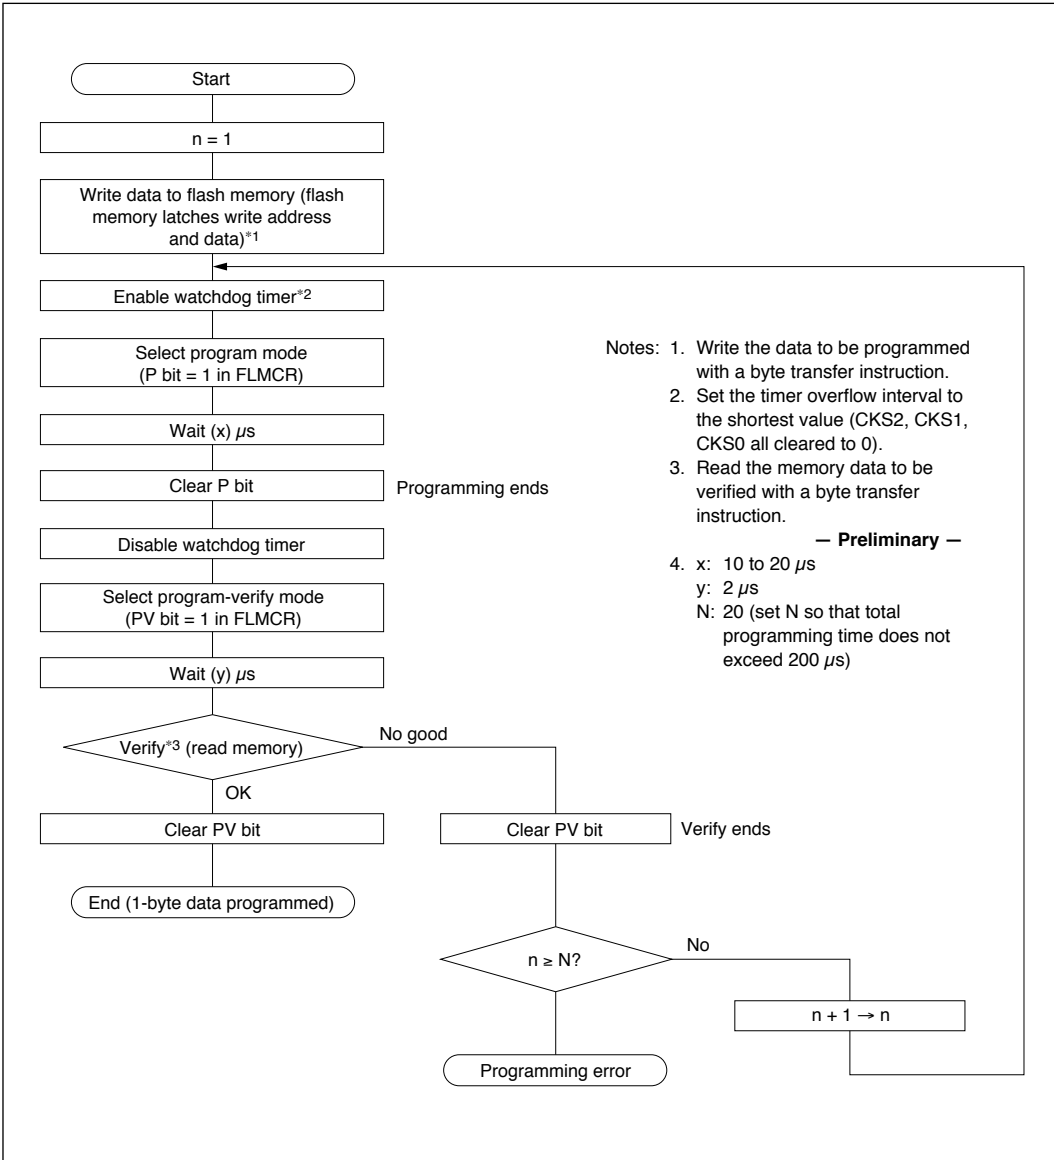

Figure 16-8 Programming Flowchart

Sample Program for Programming One Byte: This program uses the following registers.

R0: Program-verify fail counter

R1: Program and program-verify timing loop counter

R2: Stores the address to be programmed as word data. Valid addresses are H'0000 to H'EE7F.

R3: Stores data to be programmed as byte data

Arbitrary data can be programmed at an arbitrary address by setting the address in R2 and the data in R3.

The values of #a and #b depend on the clock frequency. They can be calculated as indicated under table 16-8.

```

One byte programmed

NGEND: Programming error

16.4.4 Erase Mode

To erase the flash memory, follow the erasing algorithm shown in figure 16-9. This erasing algorithm can erase data without subjecting the device to voltage stress or impairing the reliability of programmed data.

To erase flash memory, before starting to erase, first place all memory data in all blocks to be erased in the programmed state (program all memory data to H'00). If all memory data is not in the programmed state, follow the sequence described later to program the memory data to zero. Select the flash memory areas to be erased with erase block registers 1 and 2 (EBR1 and EBR2). Next set the E bit in FLPCR, selecting erase mode. The erase time is the time during which the E bit is set. To prevent overerasing, use a software timer to divide the erase time into repeated 50-ms intervals. **Overerasing, due to program runaway for example, can give memory cells a negative threshold voltage and cause them to operate incorrectly. Before selecting erase mode, set up the watchdog timer so as to prevent overerasing.**

16.4.5 Erase-Verify Mode

In program-verify mode, after data has been erased, it is read to check that it has been erased correctly. After the erase time has elapsed, exit erase mode (clear the E bit to 0) and select erase-verify mode (set the EV bit to 1). Before reading data in erase-verify mode, write H'FF dummy data to the address to be read. This dummy write applies an erase-verify voltage to the memory cells at the latched address. If the flash memory is read in this state, the data at the latched address will be read. After selecting erase-verify mode, wait 2 μ s before reading. If the read data has been successfully erased, perform the dummy write and erase-verify for the next address. If the read data has not been erased, select erase mode again and repeat the same erase and erase-verify sequence through the last address, until all memory data has been erased to 1. Do not repeat the erase and erase-verify sequence more than 600 times, however.

16.4.6 Erasing Flowchart and Sample Program

Flowchart for Erasing One Block

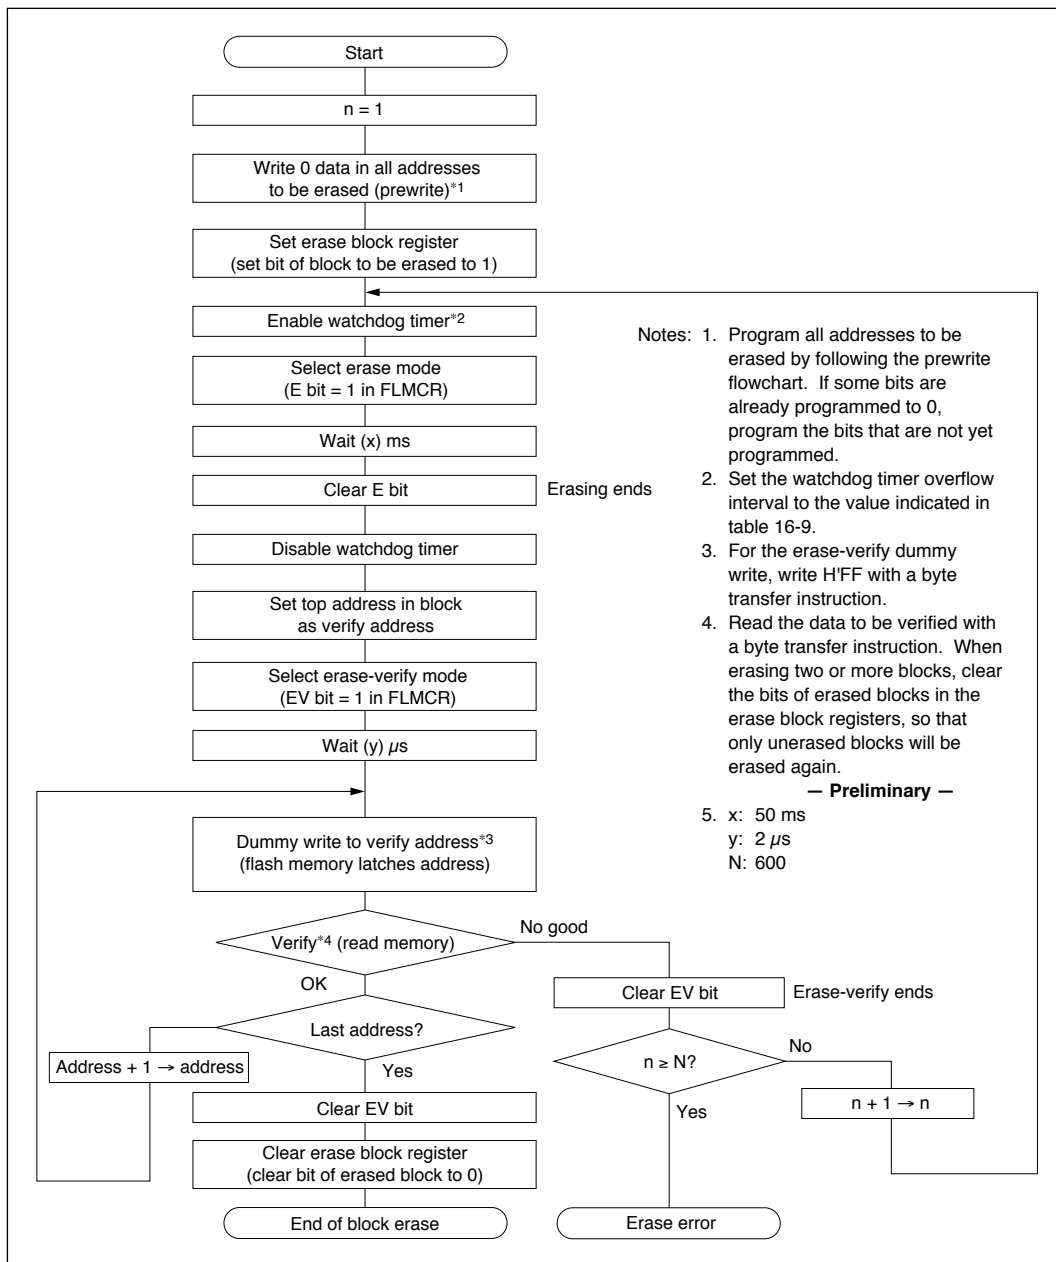

Figure 16-9 Erasing Flowchart

Prewrite Flowchart

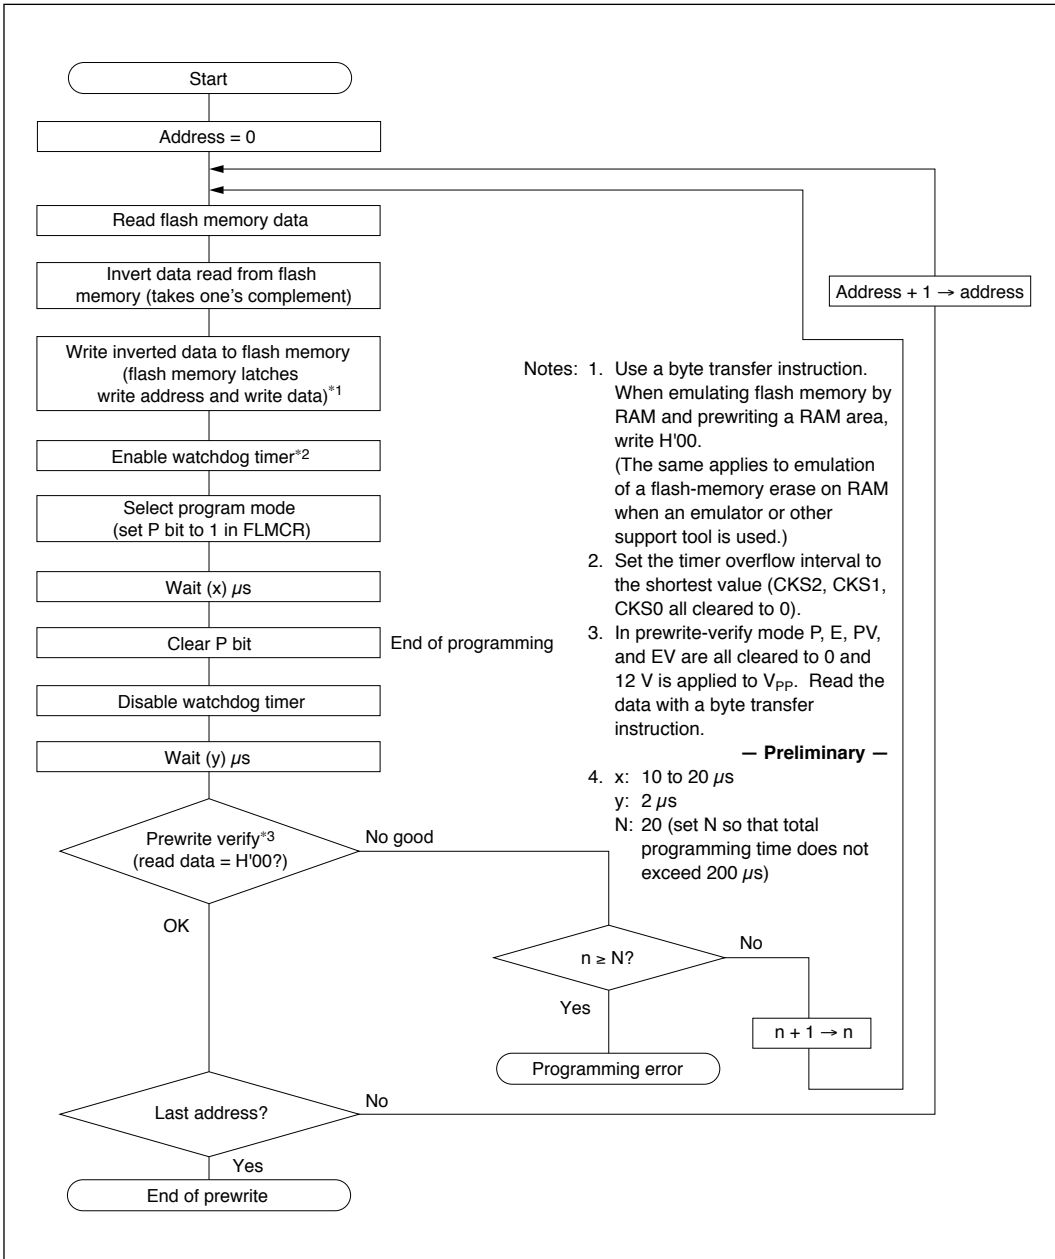

Figure 16-10 Prewrite Flowchart

Sample Block-Erase Program: This program uses the following registers.

- R0: Prewrite-verify and erase-verify fail counter
- R1: Stores address used in prewrite
- R2: Stores address used in prewrite and erase-verify.
- R3: Stores data used in erase-verify.
- R4: Timing loop counter

The values of #a, #c, #d, #e, and #f in the program depend on the clock frequency. They can be calculated as indicated in tables 16-8 and 16-9.

Flowchart for Erasing Multiple Blocks

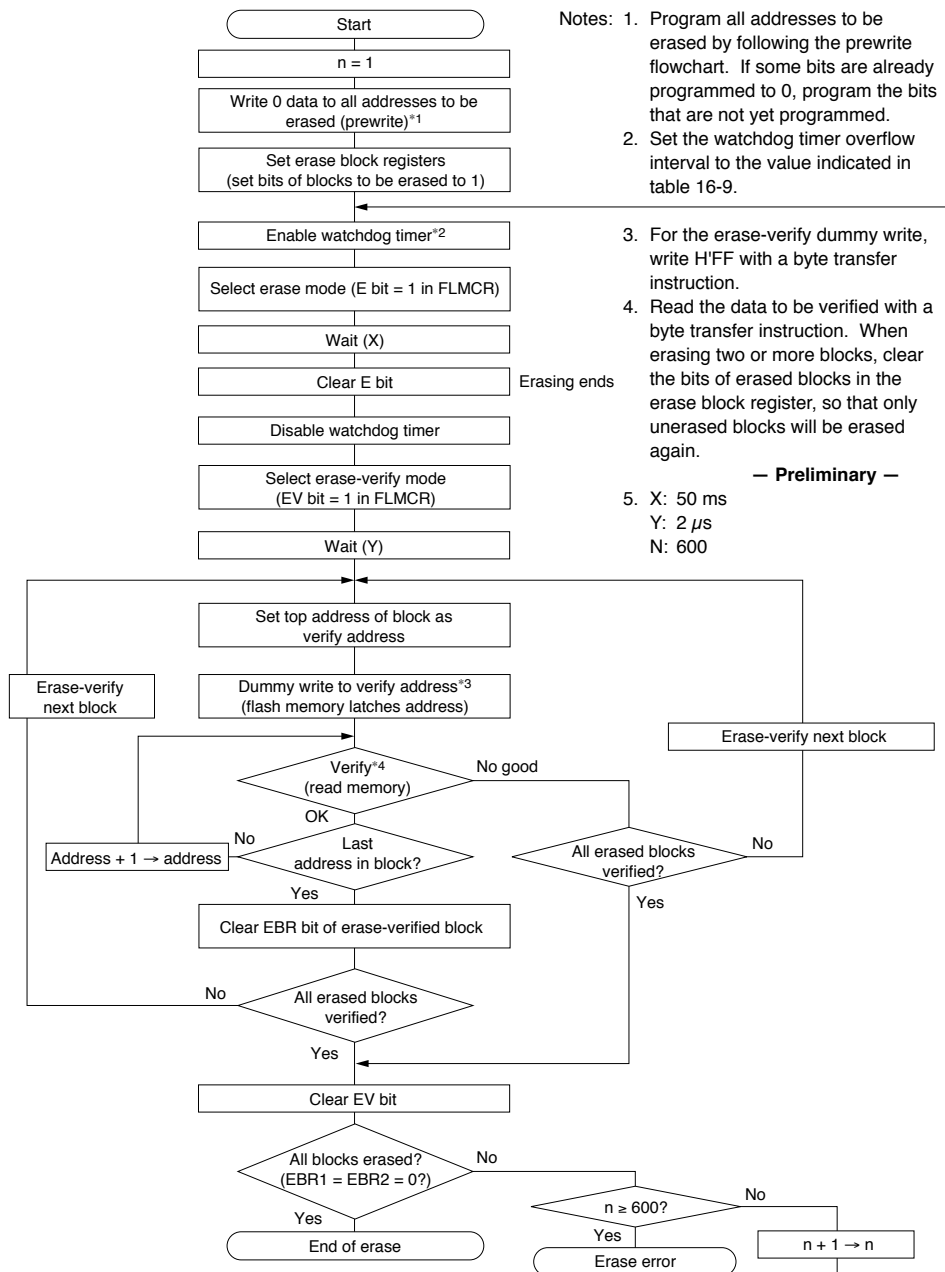

Figure 16-11 Multiple-Block Erase Flowchart

Sample Multiple-Block Erase Program: This program uses the following registers.

- R0: Specifies blocks to be erased (set as explained below)
- R1: Used to test bits 0 to 15 of R0
- R2: Specifies address where address used in prewrite and erase-verify is stored
- R3: Stores address used in prewrite and erase-verify
- R4: Stores address used in prewrite and erase-verify
- R5: Timing loop counter
- R6: Program-verify and erase-verify fail counter

Arbitrary blocks can be erased by setting bits in R0.

A bit map of R0 and an example setting for erasing specific blocks are shown next.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R0	—	LB6	LB5	LB4	LB3	LB2	LB1	LB0	SB7	SB6	SB5	SB4	SB3	SB2	SB1	SB0
	Corresponds to EBR1								Corresponds to EBR2							

Note: Clear bit 15 to 0.

Example: to erase blocks LB2, SB7, and SB0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R0	—	LB6	LB5	LB4	LB3	LB2	LB1	LB0	SB7	SB6	SB5	SB4	SB3	SB2	SB1	SB0
	Corresponds to EBR1								Corresponds to EBR2							

Setting	0	0	0	0	0	1	0	0	1	0	0	0	0	0	0	1
---------	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---

R0 is set as follows:

```
MOV.W    #0481,    @EBR1
```

The values of #a, #c, #d, #e, and #f in the program depend on the clock frequency. They can be calculated as indicated in tables 16-8 and 16-9.

For #RAMSTR in the program, substitute the starting destination address in RAM, to be used when this program is moved from flash memory into RAM.

Loop Counter Values in Programs and Watchdog Timer Overflow Interval Settings: The values of a to f in the programs depend on the clock frequency. Table 16-8 indicates the values for 10 MHz. Values for other frequencies can be calculated as shown below, but use the settings in table 16-9 for the value of f.

Table 16-8 Loop Counter Values in Program (10 MHz)

Clock Frequency		Variable				
		a (f)	b (f)	c (f)	d (f)	e (f)
f = 10 MHz	Hexadecimal	H'0016	H'0002	H'0002	H'6C80	H'0002
	Decimal	22	2	2	27776	2

Formula:

$$a(f) \text{ to } e(f) = \frac{\text{Clock frequency } f \text{ [MHz]}}{10} \times a(f=10) \text{ to } e(f=10)$$

Examples for 16 MHz:

$$\begin{aligned} a(f) &= \frac{16}{10} \times 22 = 35 \approx \text{H}'0023 \\ b(f) &= \frac{16}{10} \times 2 = 3.2 \approx \text{H}'0003 \\ c(f) &= \frac{16}{10} \times 2 = 3.2 \approx \text{H}'0003 \\ d(f) &= \frac{16}{10} \times 27776 = 44441.6 \approx \text{H}'AD99 \\ e(f) &= \frac{16}{10} \times 2 = 3.2 \approx \text{H}'0003 \end{aligned}$$

Table 16-9 Watchdog Timer Overflow Interval Settings

Clock Frequency	Variable
	f
10 MHz ≤ frequency ≤ 16 MHz	H'A57F
2 MHz ≤ frequency < 10 MHz	H'A57E

16.4.7 Prewrite Verify Mode

Prewrite-verify mode is a verify mode used when programming all bits to equalize their threshold voltages before erasing them.

To program all bits, follow the prewrite algorithm shown in figure 16-10. The procedure is to program all flash memory data to H'00 by programming the data already stored in the flash memory with 1 and 0 inverted* (one's complement). After the necessary programming time has elapsed, exit program mode (by clearing the P bit to 0) and select prewrite-verify mode (leave the P, E, PV, and EV bits all cleared to 0). In prewrite-verify mode, a prewrite-verify voltage is applied to the memory cells at the read address. If the flash memory is read in this state, the data at the read address will be read. After selecting prewrite-verify mode, wait 2 μ s before reading.

Note: For a sample prewriting program, see the prewrite subroutine in the sample erasing program.

- * When prewriting a RAM area during emulation of flash memory by RAM, write H'00 instead of inverted data.
(The same applies to emulation of a flash-memory erase on RAM when an emulator or other support tool is used.)

16.4.8 Protect Modes

Flash memory can be protected from programming and erasing by software or hardware methods. These two protection modes are described below.

Software Protection: Prevents transitions to program mode and erase mode even if the P or E bit is set in the flash memory control register (FLMCR). Details are as follows.

Protection	Description	Function		
		Program	Erase	Verify* ¹
Block protect	Individual blocks can be erase-protected by the erase block registers (EBR1 and EBR2). This form of protection does not prevent programming. If EBR1 and EBR2 are both set to H'00, all blocks are erase-protected.	Enabled	Disabled	Enabled
Emulation protect* ²	When the RAMS bit is set in the RAM control register (RAMCR), all blocks are protected from both programming and erasing.	Disabled	Disabled* ³	Enabled

Hardware Protection: Suspends or disables the programming and erasing of flash memory, and resets the flash memory control register (FLMCR) and erase block registers (EBR1 and EBR2). The error-protect function permits the P and E bits to be set, but prevents transitions to program mode and erase mode. Details of hardware protection are as follows.

Protection	Description	Function		
		Program	Erase	Verify*1
Programing voltage (V_{PP}) protect	When V_{PP} is not applied, FLMCR, EBR1, and EBR2 are initialized, disabling programming and erasing. To obtain this protection, V_{PP} should not exceed V_{CC} .*4	Disabled	Disabled*3	Disabled
Reset and standby protect	When a reset occurs (including a watchdog timer reset) or standby mode is entered, FLMCR, EBR1, and EBR2 are initialized, disabling programming and erasing. Note that RES input does not ensure a reset unless the RES pin is held low for at least 20 ms at power-up (to enable the oscillator to settle), or at least six system clock cycles (ϕ) during operation.	Disabled	Disabled*3	Disabled
Error protect	If an operational error is detected during programming or erasing of flash memory (FLER = 1), the FLMCR, EBR1, and EBR2 settings are preserved, but programming or erasing is aborted immediately. This type of protection can be cleared only by a reset or hardware standby.	Disabled	Disabled*3	Enabled

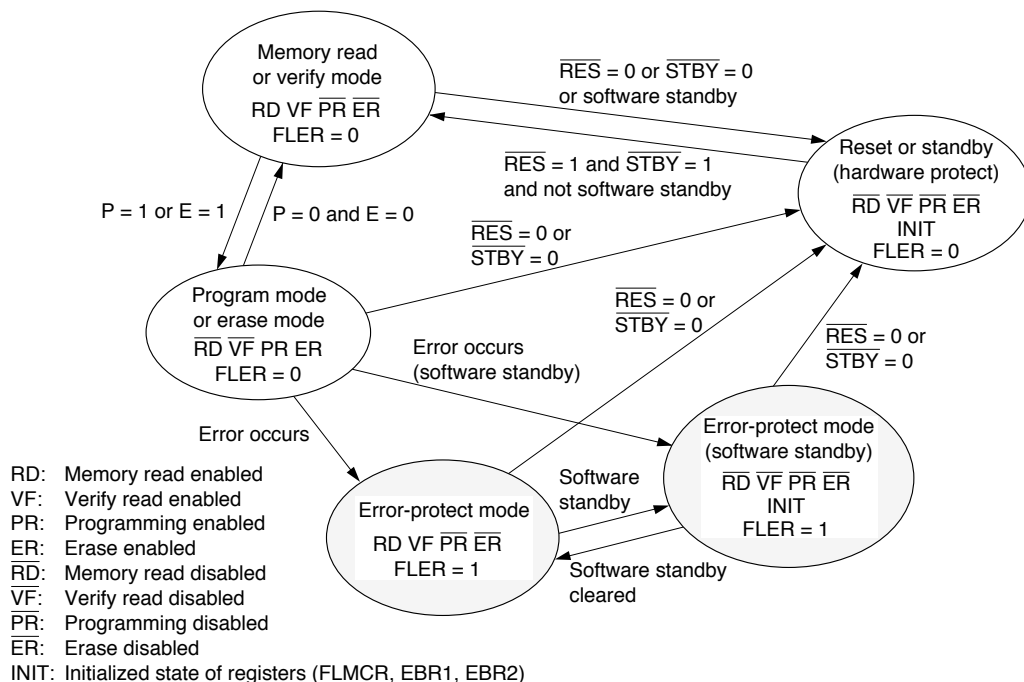

- Notes: 1. Three modes: program-verify, erase-verify, and prewrite-verify.
2. Except in RAM areas overlapped onto flash memory.
3. All blocks are erase-disabled. It is not possible to specify individual blocks.
4. For details, see section 16.7, “Flash Memory Programming and Erasing Precautions.”

Error Protect: This protection mode is entered if one of the error conditions that set the FLER bit in RAMCR*1 is detected while flash memory is being programmed or erased (while the P bit or E bit is set in FLMCR). These conditions can occur if microcontroller operations do not follow the programming or erasing algorithm. Error protect is a flash-memory state. It does not affect other microcontroller operations.

In this state the settings of the flash memory control register (FLMCR) and erase block registers (EBR1 and EBR2) are preserved,*2 but program mode or erase mode is terminated as soon as the error is detected. While the FLER bit is set, it is not possible to enter program mode or erase mode, even by setting the P bit or E bit in FLMCR again. The PV and EV bits in FLMCR remain valid, however. Transitions to verify modes are possible in the error-protect state.

The error-protect state can be cleared only by a reset or entry to hardware standby mode.

- Notes:
1. For the detailed conditions that set the FLER bit, see section 16.2.4, “RAM Control Register (RAMCR).”
 2. It is possible to write to these registers. Note that a transition to software standby mode initializes these registers.

Flash Memory State Transitions
[in Modes 2, 4, and 7 (On-Chip ROM Enabled) when Programming Voltage (V_{PP}) is Applied]

The purpose of error-protect mode is to prevent overprogramming or overerasing damage to flash memory by detecting abnormal conditions that occur if the programming or erasing algorithm is not followed, or if a program crashes while the flash memory is being programmed or erased.

This protection function does not cover abnormal conditions other than the setting conditions of the flash memory error bit (FLER), however. Also, if too much time elapses before the error-protect state is reached, the flash memory may already have been damaged. This function accordingly does not offer foolproof protection from damage to flash memory.

To prevent abnormal operations, when programming voltage (V_{PP}) is applied, follow the programming and erasing algorithms correctly, and keep microcontroller operations under constant internal and external supervision, using the watchdog timer for example. If a transition to

error-protect mode occurs, the flash memory may contain incorrect data due to errors in programming or erasing, or it may contain data that has been insufficiently programmed or erased because of the suspension of these operations. Boot mode should be used to recover to a normal state.

If the memory contains overerased memory cells, boot mode may not operate correctly. This is because the H8/538F's built-in boot program is located in part of flash memory, and will not read correctly if memory cells have been overerased.

16.4.9 NMI Input Masking

NMI input is disabled when flash memory is being programmed or erased (when the P or E bit is set in FLMCR). NMI input is also disabled while the boot program is executing in boot mode, until the branch to the on-chip RAM area takes place.*¹ There are three reasons for this.

1. NMI input during programming or erasing might cause a violation of the programming or erasing algorithm. Normal operation could not be assured.
2. In the NMI exception-handling sequence during programming or erasing, the vector would not be read correctly.*² The result might be a program runaway.
3. If NMI input occurred during boot program execution, the normal boot-mode sequence could not be executed.

For these reasons, under certain conditions the H8/538F masks the normally nonmaskable NMI input. This masking does not, however, ensure normal programming, erasing, and other microcontroller operations. NMI requests should be disabled externally whenever V_{pp} is applied.

NMI input is also disabled in the error-protect state while the P or E bit remains set in the flash memory control register (FLMCR).

- Notes:
1. The disabled state lasts until the branch to the boot program area in on-chip RAM (addresses H'F680 to H'F8FF) that takes place as soon as the transfer of the user program is completed. After the branch to the RAM area, NMI input is enabled except during programming or erasing. NMI interrupt requests must therefore be disabled externally until the user program has completed initial programming (including the vector table and the NMI interrupt-handling program).
 2. The vector may not be read correctly for the following two reasons.
 - a. If flash memory is read while being programmed or erased (while the P or E bit is set in FLMCR), correct read data will not be obtained. Undetermined values are returned.
 - b. If the NMI entry in the vector table has not been programmed yet, NMI exception handling will not be executed correctly.

16.5 Flash Memory Emulation by RAM

Erasing and programming flash memory takes time, which can make it difficult to tune parameters and other data in real time. If necessary, real-time updates of flash memory can be emulated by overlapping the small-block flash-memory area with part of the RAM (H'F680 to H'F6FF). This RAM reassignment is performed using bits 3 to 0 of the RAM control register (RAMCR).

After a flash memory area has been overlapped by RAM, it can be accessed from two address areas: the overlapped flash memory area, and the original RAM area (H'F680 to H'F6FF). RAMCR bits 3 to 0 are valid in user program mode and boot mode. In other modes, they always read 0 and the RAM area cannot be reassigned. Table 16-10 indicates how to reassign RAM.

RAM Control Register (RAMCR)

Bit	7	6	5	4	3	2	1	0
	RAME	—	—	FLER	RAMS	RAM2	RAM1	RAM0
Initial value* ¹	1	Undetermined* ²	1	0	0	0	0	0
R/W	R/W	—	—	R	R/W* ³	R/W* ³	R/W* ³	R/W* ³

- Notes:
1. Bit 7 and bits 4 to 0 are initialized by a reset and in hardware standby mode. They are not initialized in software standby mode. Bits 3 to 0 are also initialized when 12 V is not applied to the V_{PP} pin.
 2. Bit 6 is reserved for chip testing and has an undetermined value when written or read.
 3. Bits 3 to 0 can be modified in user program mode and boot mode.

Table 16-10 RAM Area* Reassignment

RAM Area*	Bit 3	Bit 2	Bit 1	Bit 0	Reassignment	Program/Erase Protection
	RAMS	RAM2	RAM1	RAM0		
(H'F680 to H'F6FF)	0	0/1	0/1	0/1	Disabled	Disabled
H'EC00 to H'EC7F	1	0	0	0	Enabled	Enabled
H'EC80 to H'ECFF	1	0	0	1	Enabled	Enabled
H'ED00 to H'ED7F	1	0	1	0	Enabled	Enabled
H'ED80 to H'EDFF	1	0	1	1	Enabled	Enabled
H'EE00 to H'EE7F	1	1	0	0	Enabled	Enabled
(H'F680 to H'F6FF)	1	1	0	1	Disabled	Enabled
	1	1	1	0		
	1	1	1	1		

Note: * Flash-memory addresses overlapped by RAM.

Example of Emulation of Real-Time Flash-Memory Update

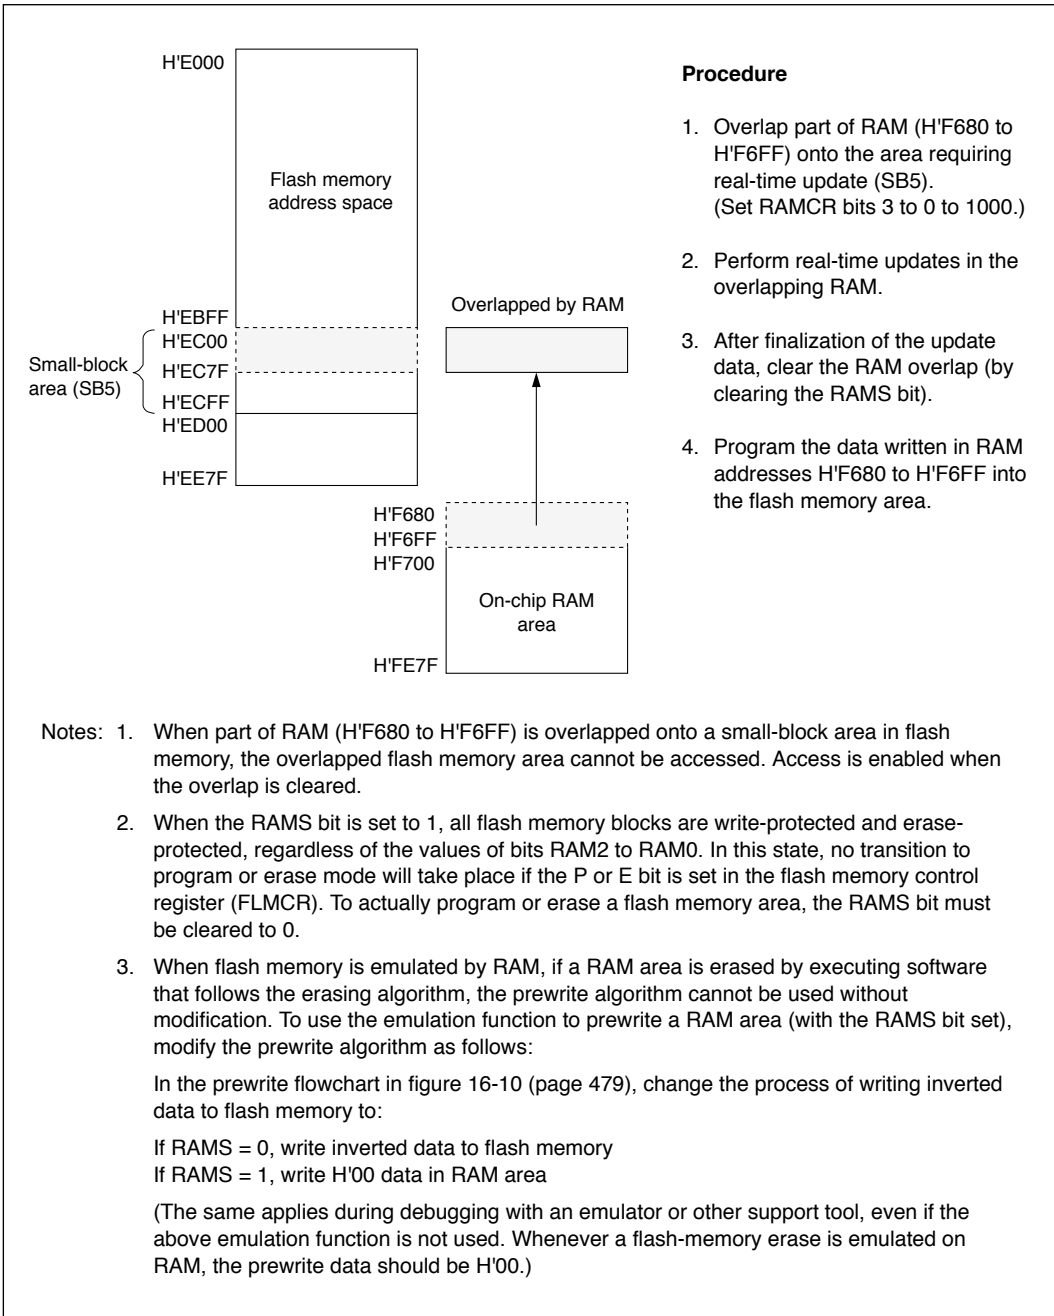

Figure 16-12 Example of RAM Overlap

16.6 PROM Mode

16.6.1 PROM Mode Setting

The on-chip flash memory of the H8/538F can be programmed and erased not only in the on-board programming modes but also in PROM mode, using a general-purpose PROM programmer. Table 16-11 indicates how to select PROM mode.

Table 16-11 Selecting PROM Mode

Pins	Setting
Mode pins: MD ₂ , MD ₁ , MD ₀	Low
P6 ₁ and P7 ₃	
STBY and HWR	High
PA ₀ , PA ₁ , and P6 ₀	
RES	Power-on reset circuit
XTAL and EXTAL	Oscillator circuit

16.6.2 Socket Adapter and Memory Map

Programs can be written and verified by attaching a special 120-pin/32-pin or 112-pin/32-pin socket adapter to the PROM programmer. Table 16-12 gives ordering information for the socket adapter. Figure 16-13 shows a memory map in PROM mode. Figure 16-14 shows the socket adapter pin interconnections.

Table 16-12 Socket Adapter

Microcontroller	Package	Socket Adapter
HD64F5388F	112-pin plastic QFP (FP-112)	HS538FESH01H
HD64F5388TF	120-pin plastic TQFP (TFP-120)	HS538FESN01H*

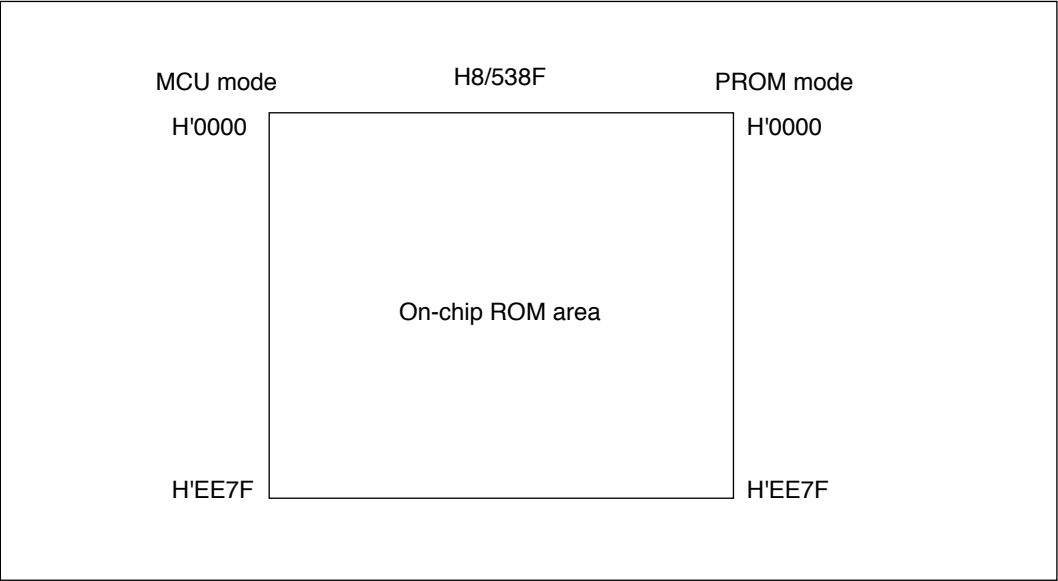

Figure 16-13 Memory Map in PROM Mode

Note: * The TQFP-120 pin pitch is only 0.4 mm. Use an appropriate tool when inserting the device in the IC socket and removing it. For example, the tool listed in table 16-13 can be used.

Table 16-13

High-Speed, High-Reliability Programming: Unused areas of the H8/538F flash memory contain H'FF data (initial value). The H8/538F flash memory uses a high-speed, high-reliability programming procedure. This procedure provides enhanced programming speed without subjecting the device to voltage stress and without sacrificing the reliability of programmed data. Figure 16-15 shows the basic high-speed, high-reliability programming flowchart. Tables 16-16 and 16-17 list the electrical characteristics during programming.

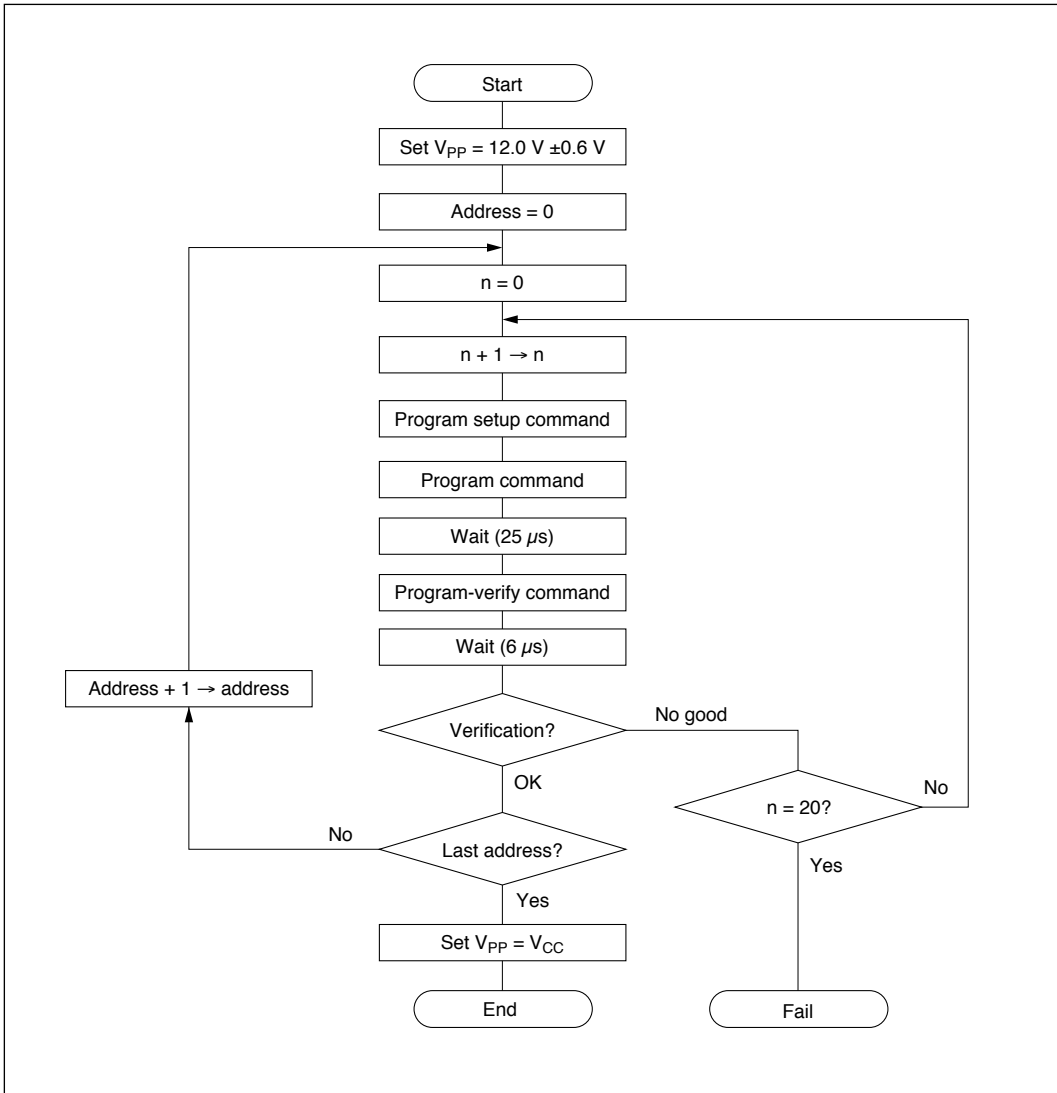

Figure 16-15 High-Speed, High-Reliability Programming

High-Speed, High-Reliability Erasing: The H8/538F flash memory uses a high-speed, high-reliability erasing procedure. This procedure provides enhanced erasing speed without subjecting the device to voltage stress and without sacrificing data reliability . Figure 16-16 shows the basic high-speed, high-reliability erasing flowchart. Tables 16-16 and 16-17 list the electrical characteristics during programming.

Figure 16-18 High-Speed, High-Reliability Programming Timing

Note: Erase-verify data output values may be intermediate between 1 and 0 if erasing is insufficient.

Figure 16-19 Erase Timing

16.7 Flash Memory Programming and Erasing Precautions

(1) Program with the specified voltages and timing.

The rated programming voltage (V_{PP}) of the flash memory is 12.0 V.

If the PROM programmer is set to Hitachi HN28F101 specifications, V_{PP} will be 12.0 V. Applied voltages in excess of the rating can permanently damage the device. Be particularly careful about PROM programmer overshoot.

(2) Before programming, check that the chip is correctly mounted in the PROM programmer. Overcurrent damage to the device can result if the index marks on the PROM programmer socket, socket adapter, and chip are not correctly aligned.

(3) Don't touch the socket adapter or chip while programming. Touching either of these can cause contact faults and write errors.

(4) Set H'FF as the PROM programmer buffer data for addresses H'EE80 to H'1FFFF. The H8/538F PROM size is 60 kbytes. Addresses H'EE80 to H'1FFFF always read H'FF, so if H'FF is not specified as programmer data, a verify error will occur.

(5) Precautions in turning the programming voltage (V_{PP}) on and off:

(a) Apply the programming voltage (V_{PP}) after the rise of V_{CC} , when the microcontroller is in a stable condition. Shut off V_{PP} before V_{CC} , again while the microcontroller is in a stable condition. If V_{PP} is turned on or off while V_{CC} is not within its rated voltage range ($V_{CC} = 2.7$ to 5.5 V), since microcontroller operation is unstable and flash memory protection is not functioning, the flash memory may be programmed or erased by mistake. This can occur even if $V_{CC} = 0$ V. The same danger of incorrect programming or erasing exists when V_{CC} is within its rated voltage range ($V_{CC} = 2.7$ to 5.5 V) if the clock oscillator has not stabilized, if the clock oscillator has stopped (except in standby), or if a program runaway has occurred. After V_{CC} power-up, do not apply V_{PP} until the clock oscillator has had time to settle ($t_{OSC1} = 20$ ms min) and the microcontroller is safely in the reset state, or the reset has been cleared.

These power-on and power-off timing requirements should also be satisfied in the event of a power failure and recovery from a power failure. If these requirements are not satisfied, the flash memory may not only be unintentionally programmed or erased; it may be permanently damaged.

(b) Do not read flash memory while V_{PP} is being switched on or off. Flash memory cannot be read normally at the instant when V_{PP} is switched on or off (undetermined data will be read). If V_{PP} is switched on or off while the CPU is executing a program in flash memory, the program may start running out of control. This also applies to boot mode, because the H8/538F's built-in boot program is stored in part of flash memory. **V_{PP} should be turned on or off only in the reset**

(c) The **V_{PP}** flag is set and cleared by a threshold decision on the voltage applied to **V_{PP}**. The threshold level is between approximately **V_{CC} + 2 V** and **V_{CC} + 5 V**. When this flag is set, it becomes possible to write to the flash memory control register (FLMCR), the erase block registers (EBR1 and EBR2), and bits 3 to 0 in the RAM control register (RAMCR), even though the **V_{PP}** voltage may not yet have reached the programming voltage range of **12.0 ± 0.6 V**. **Do not actually program or erase the flash memory until V_{PP} has reached the programming voltage range.** **V_{PP}** should be turned on and off only when the P and E bits in FLMCR are cleared. Be sure that these bits are not set by mistaken access to FLMCR.

The programming voltage range for programming and erasing flash memory is 12.0 ± 0.6 V (11.4 V to 12.6 V). Programming and erasing cannot be performed correctly outside this range. **When not programming or erasing the flash memory, ensure that the V_{PP} voltage does not exceed the V_{CC} voltage. This will prevent unintended programming and erasing.**

Figure 16-20 V_{PP} Power-On and Power-Off Timing

(6) Disable watchdog-timer reset output ($\overline{\text{RESO}}$) while the programming voltage (V_{PP}) is turned on. If 12 V is applied during watchdog timer reset output (while the $\overline{\text{RESO}}$ pin is low), overcurrent flow will permanently destroy the reset output circuit. The watchdog timers reset output enable bit (RSTOE) should not be set to 1.

If the watchdog timer generates a reset output signal when 12 V is not applied, the rise and fall of the reset output waveform will be delayed by any decoupling capacitors connected to the V_{PP} pin.

(7) Design a current margin into the programming voltage (V_{PP}) power supply. Ensure that V_{PP} will not depart from 12.0 ± 0.6 V (11.4 V to 12.6 V) during programming or erasing. Programming and erasing may become impossible outside this range. Connect decoupling capacitors as close to the V_{PP} pin as possible.

Figure 16-21 V_{PP} Power Supply Circuit Design (Example)

(8) The maximum rated storage temperature range ($T_{\text{stg}} = -55$ to 125°C) applies to erased data. It does not guarantee data retention. Programmed data may be lost.

(9) Do not apply 12 V to the V_{PP} pin during normal operation. To prevent microcontroller errors caused by accidental programming or erasing, apply 12 V to V_{PP} only when the flash memory is programmed or erased, or when flash memory is emulated by RAM. While 12 V is applied, the watchdog timer should be running and enabled to halt runaway program execution, so that program runaway will not lead to overprogramming or overerasing.

Section 17 Power-Down State

17.1 Overview

The H8/538F has a power-down state that greatly reduces power consumption by halting CPU functions. The power-down state includes three modes: sleep mode, software standby mode, and hardware standby mode. Table 17-1 gives the methods of entering and exiting the power-down modes.

Table 17-1 Power-Down Mode Transition Conditions

Mode	Entering Procedure	State						Exiting Methods
		Clock	CPU	CPU Registers	Peripheral Functions	RAM	I/O Ports	
Sleep mode	Execute SLEEP instruction	Run	Halt	Held	Run	Held	Held	<ul style="list-style-type: none"> • Interrupt • $\overline{\text{RES}}$ • $\overline{\text{STBY}}$
Software standby mode	Set SSBY bit in SBYCR to 1, then execute SLEEP instruction	Halt	Halt	Held	Halt and initialized	Held	Held	<ul style="list-style-type: none"> • NMI • $\overline{\text{RES}}$ • $\overline{\text{STBY}}$
Hardware standby mode	Low input at $\overline{\text{STBY}}$ pin	Halt	Halt	Not held	Halt	Held	High impedance	<ul style="list-style-type: none"> • $\overline{\text{STBY}}$ & $\overline{\text{RES}}$

Legend

SBYCR: Software standby control register

SSBY: Software standby bit

17.2 Sleep Mode

This section describes sleep mode.

17.2.1 Transition to Sleep Mode

Execution of the SLEEP instruction causes a transition from the program execution state to sleep mode. Immediately after executing the SLEEP instruction the H8/500 CPU halts, but the contents of its internal registers remain unchanged. The on-chip peripheral modules do not halt in sleep mode.

17.2.2 Exit from Sleep Mode

The chip exits sleep mode when it receives an interrupt request, or a low input at the $\overline{\text{RES}}$ or $\overline{\text{STBY}}$ pin.

(1) Exit by Interrupt: An interrupt terminates sleep mode and starts the interrupt-handling routine or data transfer controller (DTC). The chip does not exit sleep mode if the interrupt priority level is equal to or less than the level set in the H8/500 CPU's status register (SR), or if the interrupt is disabled in an on-chip peripheral module.

(2) Exit by $\overline{\text{RES}}$ Input: When the $\overline{\text{RES}}$ signal goes low, the H8/538F exits from sleep mode to the reset state.

(3) Exit by $\overline{\text{STBY}}$ Input: When the $\overline{\text{STBY}}$ signal goes low, the H8/538F exits from sleep mode to hardware standby mode.

17.3 Software Standby Mode

This section describes software standby mode.

17.3.1 Transition to Software Standby Mode

If software sets the standby bit (SSBY) to 1 in the software standby control register (SBYCR), then executes the SLEEP instruction, the H8/538F enters software standby mode. Table 17-2 gives register information about SBYCR.

In software standby mode current dissipation is reduced to an extremely low level because the CPU and on-chip peripheral modules all halt. The on-chip peripheral modules are reset. As long as the specified voltage is supplied, however, CPU register contents, on-chip RAM data, and I/O port states are held.

Table 17-2 Standby Control Register

Address	Name	Abbreviation	R/W	Initial Value
H'FF1A	Software standby control register	SBYCR	R/W	H'7F

17.3.2 Software Standby Control Register

The software standby control register (SBYCR) is an eight-bit register that must be set in order to enter software standby mode. The bit structure is described next.

Bit	7	6	5	4	3	2	1	0
	SSBY	—	—	—	—	—	—	—
Initial value	0	1	1	1	1	1	1	1
R/W	R/W	—	—	—	—	—	—	—

Reserved bits

Software standby bit
Enables transition to software standby mode

(1) Bit 7—Software Standby (SSBY): Enables transition to software standby mode.

Bit 7		
SSBY	Description	
0	SLEEP instruction causes transition to sleep mode.	(Initial value)
1	SLEEP instruction causes transition to software standby mode	

The SSBY bit cannot be set to 1 while the timer enable bit (TME) is set to 1 in the timer control/status register (TCSR) of the watchdog timer (WDT). Before entering software standby mode, software must clear the TME bit to 0.

The SSBY bit is automatically cleared to 0 when the chip recovers from software standby mode by NMI or reset, or enters hardware standby mode.

(2) Bits 6 to 0—Reserved: Read-only bits, always read as 1.

17.3.3 Exit from Software Standby Mode

The chip can be brought out of software standby mode by input at the NMI, $\overline{\text{RES}}$, or $\overline{\text{STBY}}$ pin.

(1) Recovery by NMI: To recover from software standby mode by NMI input, software must set clock select bits 2 to 0 (CKS2 to CKS0) in the watchdog timer’s timer control/status register (TCSR) beforehand to select the oscillator setting time, and must also select the desired NMI input edge.

When an NMI interrupt request signal is input, the clock oscillator begins operating. At first clock pulses are supplied only to the watchdog timer. The watchdog timer receives the supplied clock and starts counting. After the oscillator settling time selected by bits CKS2 to CKS0 in the control/status register (TCSR), the watchdog timer overflows. After the watchdog timer overflows, the clock is supplied to the entire H8/538F chip, software standby mode ends, and the NMI exception-handling sequence begins.

(2) Recovery by $\overline{\text{RES}}$ Input: When software standby mode is exited by $\overline{\text{RES}}$ input, clock pulses are supplied to the entire H8/538F chip as soon as the clock oscillator starts. The clock oscillator starts when the $\overline{\text{RES}}$ signal goes low. After the oscillator settling time, when the $\overline{\text{RES}}$ signal goes high, the CPU begins executing the reset sequence. The $\overline{\text{RES}}$ signal must be held low long enough for the clock to stabilize.

(3) Recovery by $\overline{\text{STBY}}$ Input: When the $\overline{\text{STBY}}$ signal goes low, the H8/538F exits from software standby mode to hardware standby mode.

17.3.4 Sample Application of Software Standby Mode

Figure 17-1 illustrates NMI timing for software standby mode.

- ① With the nonmaskable interrupt edge bit (NMIEG) in the NMI control register (NMICR) cleared to 0 (falling edge), NMI goes low.
- ② The NMIEG bit is set to 1.
- ③ Software sets the SSBY bit to 1, then executes the SLEEP instruction. The chip enters software standby mode.
- ④ When the NMI signal goes high, the chip exits software standby mode.

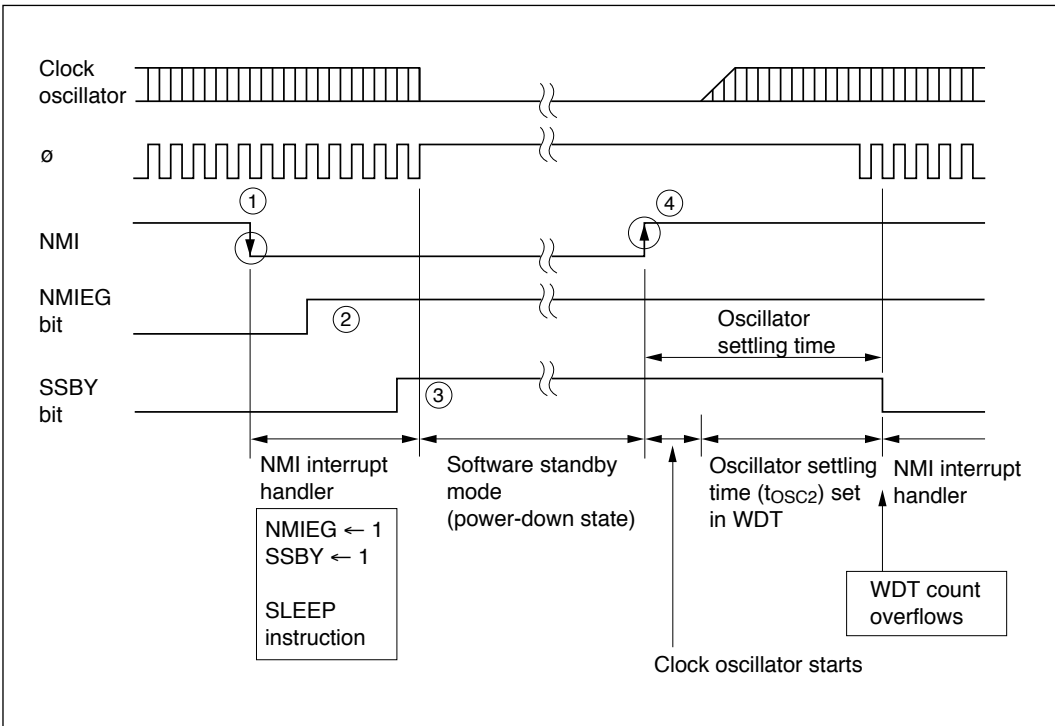

Figure 17-1 NMI Timing for Software Standby Mode (example)

17.3.5 Note

The I/O ports are not initialized in software standby mode. If a port is in the high output state, it remains in that state and power reduction is lessened by the amount of current output.

17.4 Hardware Standby Mode

This section describes hardware standby mode.

17.4.1 Transition to Hardware Standby Mode

Regardless of its current state, the chip enters hardware standby mode whenever the $\overline{\text{STBY}}$ pin goes low. Hardware standby mode reduces power consumption drastically by halting the CPU and stopping all functions of the on-chip peripheral modules. The on-chip peripheral modules are reset, but as long as the specified voltage is supplied, on-chip RAM contents are held. To hold RAM contents, the RAME bit in the RAM control register (RAMCR) should be cleared to 0. I/O ports are placed in the high-impedance state.

17.4.2 Recovery from Hardware Standby Mode

Recovery from the hardware standby mode requires inputs on both the $\overline{\text{STBY}}$ and $\overline{\text{RES}}$ lines. When $\overline{\text{STBY}}$ goes high, the clock oscillator begins running. $\overline{\text{RES}}$ should be low at this time. After the oscillator settling time, when the $\overline{\text{RES}}$ signal goes high, the H8/500 CPU begins executing the reset sequence. The H8/500 CPU then returns to the program execution state, ending hardware standby mode.

17.4.3 Timing for Hardware Standby Mode

Figure 17-2 shows the timing relationships in hardware standby mode.

Figure 17-2 Hardware Standby Mode Timing

Note: The $V_{\text{CC}} = AV_{\text{CC}}$ relationship should be maintained in the power-down state. If AV_{CC} is disconnected, the internal analog-digital interface becomes unstable, current dissipation increases, and reliability problems may occur.

Section 18 Electrical Characteristics

18.1 Absolute Maximum Ratings

Table 18-1 lists the absolute maximum ratings.

Table 18-1 Absolute Maximum Ratings

Item	Symbol	Value	Unit
Power supply voltage	V_{CC}	−0.3 to +7.0	V
Programming voltage	V_{PP}	−0.3 to +13.0	V
Input voltage (except ports 8 and 9)	V_{in}	−0.3 to $V_{CC} + 0.3$	V
Input voltage (ports 8 and 9)	V_{in}	−0.3 to $AV_{CC} + 0.3$	V
Reference voltage	V_{REF}	−0.3 to $AV_{CC} + 0.3$	V
Analog power supply voltage	AV_{CC}	−0.3 to +7.0	V
Analog input voltage	V_{AN}	−0.3 to $AV_{CC} + 0.3$	V
Operating temperature	T_{opr}	Regular specifications: −20 to +75	°C
		Wide-range specifications: −40 to +85	
Storage temperature	T_{stg}	−55 to +125	°C

Caution: Permanent damage to the chip may result if absolute maximum ratings are exceeded.

18.2 Electrical Characteristics

18.2.1 DC Characteristics

Tables 18-2 to 18-4 list the DC characteristics. Table 18-5 lists the permissible output currents.

Table 18-2 DC Characteristics [Low-Voltage Specifications (2.7-V Version)]

Conditions: $V_{CC} = 2.7$ to 5.5 V, $AV_{CC} = 2.7$ to 5.5 V, $V_{REF} = 2.7$ to 5.5 V ($V_{REF} \leq AV_{CC}$),

2. Current dissipation values are for $V_{IHmin} = V_{CC} - 0.5\text{ V}$ and $V_{ILmax} = 0.5\text{ V}$ with all output pins unloaded and the on-chip pull-up transistors in the off state.

Table 18-5 Permissible Output Currents

Condition A: $V_{CC} = 2.7$ to 5.5 V, $AV_{CC} = 2.7$ to 5.5 V, $V_{REF} = 2.7$ to 5.5 V ($V_{REF} \leq AV_{CC}$),
 $V_{SS} = AV_{SS} = 0$ V, $T_a = -20$ to $+75^\circ\text{C}$ (regular specifications)

Condition B: $V_{CC} = 3.0$ to 5.5 V, $AV_{CC} = 3.0$ to 5.5 V, $V_{REF} = 3.0$ to 5.5 V ($V_{REF} \leq AV_{CC}$),
 $V_{SS} = AV_{SS} = 0$ V, $T_a = -20$ to $+75^\circ\text{C}$ (regular specifications)

Condition C: $V_{CC} = 5.0$ V $\pm 10\%$, $AV_{CC} = 5.0$ V $\pm 10\%$, $V_{REF} = 5.0$ V $\pm 10\%$ ($V_{REF} \leq AV_{CC}$),
 $V_{SS} = AV_{SS} = 0$ V, $T_a = -20$ to $+75^\circ\text{C}$ (regular specifications), $T_a = -40$ to $+85^\circ\text{C}$ (wide-range specifications)

Item	Symbol	Conditions A, B, and C			Unit
		Min	Typ	Max	
Permissible output low current (per pin)	Ports 3 and 5	I_{OL}	—	—	10 mA
	RESO		—	—	3.0 mA
	Other output pins		—	—	2.0 mA
Permissible output low current (total)	Total of 13 pins in ports 3 and 5	ΣI_{OL}	—	—	40 mA
	Total of all output pins, including the above		—	—	80 mA
Permissible output high current (per pin)	All output pins	I_{OH}	—	—	2.0 mA
Permissible output high current (total)	Total of all output pins	ΣI_{OH}	—	—	25 mA

- Notes: 1. To protect chip reliability, do not exceed the output current values in table 18-5.
2. When driving a Darlington pair or LED, always insert a current-limiting resistor in the output line, as shown in figures 18-1 and 18-2.

Figure 18-1 Darlington Pair Drive Circuit (Example)

Figure 18-2 LED Drive Circuit (Example)

18.2.2 AC Characteristics

The AC characteristics of the H8/538F are described below. Bus timing parameters are listed in table 18-6. Control signal timing parameters are listed in table 18-7. Timing parameters of the on-chip peripheral modules are listed in table 18-8.

Table 18-6 Bus Timing

Condition A: $V_{CC} = 2.7$ to 5.5 V, $AV_{CC} = 2.7$ to 5.5 V, $V_{REF} = 2.7$ to 5.5 V, $V_{SS} = AV_{SS} = 0$ V, $T_a = -20$ to $+75^\circ\text{C}$ (regular specifications)

Condition B: $V_{CC} = 3.0$ to 5.5 V, $AV_{CC} = 3.0$ to 5.5 V, $V_{REF} = 3.0$ to 5.5 V, $V_{SS} = AV_{SS} = 0$ V, $T_a = -20$ to $+75^\circ\text{C}$ (regular specifications)

Condition C: $V_{CC} = 5.0$ V $\pm 10\%$, $AV_{CC} = 5.0$ V $\pm 10\%$, $V_{REF} = 5.0$ V $\pm 10\%$, $V_{SS} = AV_{SS} = 0$ V, $T_a = -20$ to $+75^\circ\text{C}$ (regular specifications), $T_a = -40$ to $+85^\circ\text{C}$ (wide-range specifications)

Allowable signal-source impedance	$8.38\ \mu\text{s} \leq \text{conversion time} \leq 13.4\ \mu\text{s}$	—	—	5	k Ω
	$2.7\ \text{V} \leq AV_{CC} < 4.5\ \text{V}$				
	Other conditions	—	—	10	

18.3 Operational Timing

This section shows timing diagrams of H8/538F operations.

18.3.1 Bus Timing

This section gives the following H8/538F bus timing diagrams:

1. Basic bus cycle: two-state access

Figure 18-4 shows the timing of the external two-state access cycle.

2. Basic bus cycle: three-state access

Figure 18-5 shows the timing of the external three-state access cycle.

3. Basic bus cycle: three-state access with one wait state

Figure 18-6 shows the timing of the external three-state access cycle with one wait state inserted.

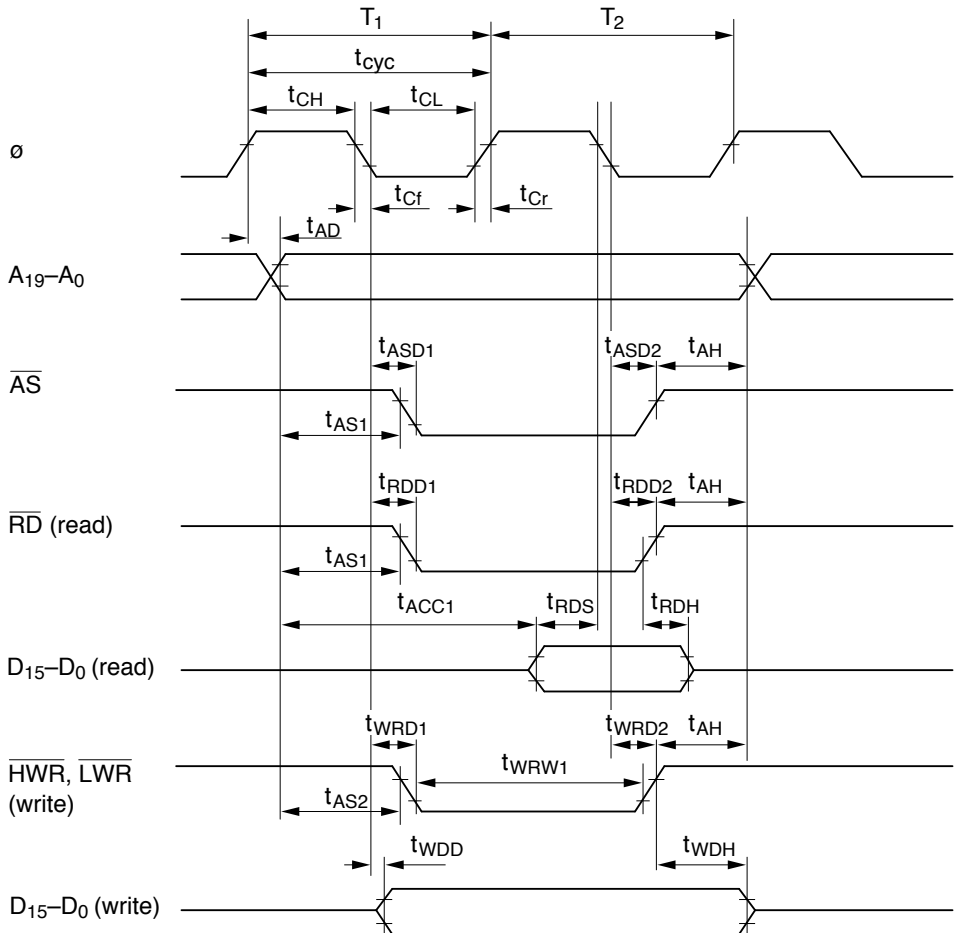

Figure 18-4 Basic Bus Cycle: Two-State Access

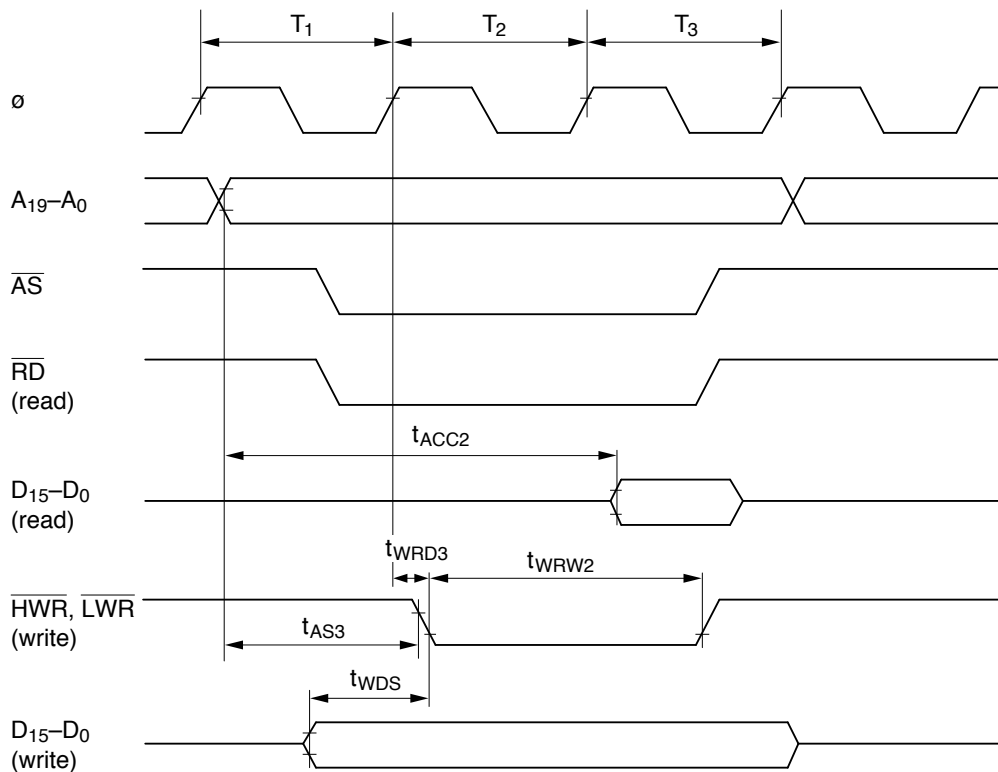

Figure 18-5 Basic Bus Cycle: Three-State Access

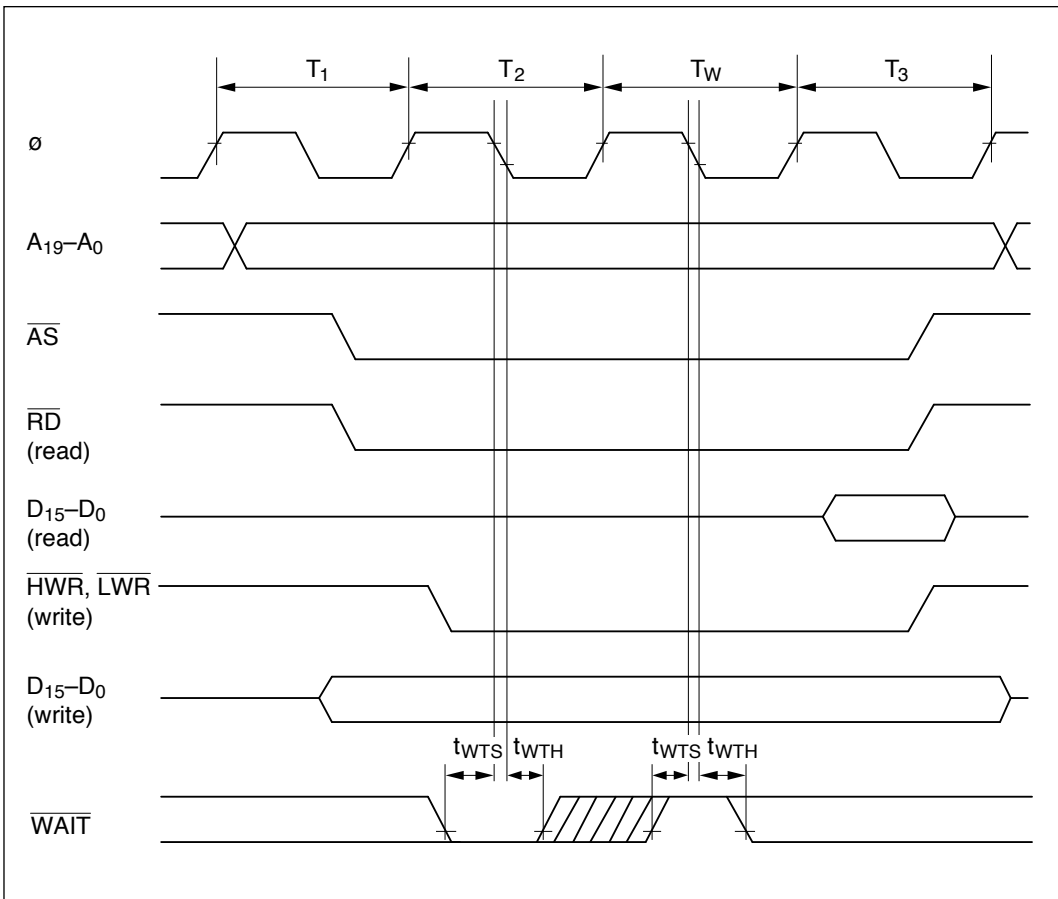

Figure 18-6 Basic Bus Cycle: Three-State Access with One Wait State

18.3.2 Control Signal Timing

This section gives the following H8/538F control signal timing diagrams:

1. Reset input timing

Figure 18-7 shows the reset input timing.

2. Reset output timing

Figure 18-8 shows the reset output timing.

3. Interrupt input timing

Figure 18-9 shows the input timing for NMI, $\overline{\text{IRQ}}_0$, and $\overline{\text{IRQ}}_1$ to $\overline{\text{IRQ}}_3$.

4. Bus-release mode timing

Figure 18-10 shows the bus-release mode timing.

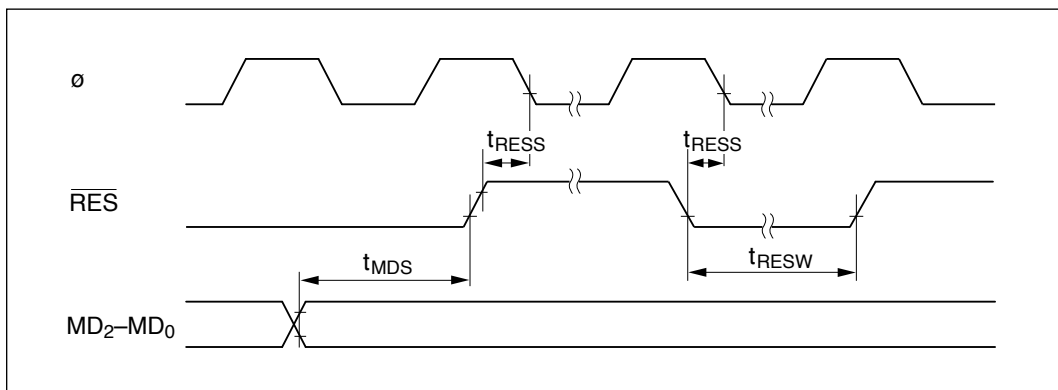

Figure 18-7 Reset Input Timing

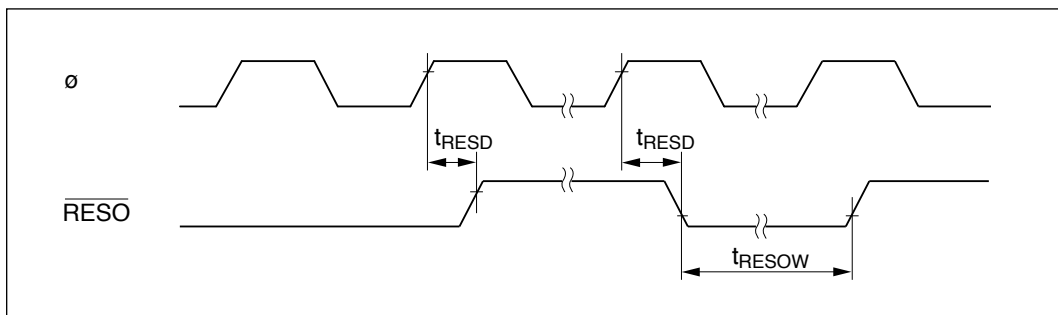

Figure 18-8 Reset Output Timing

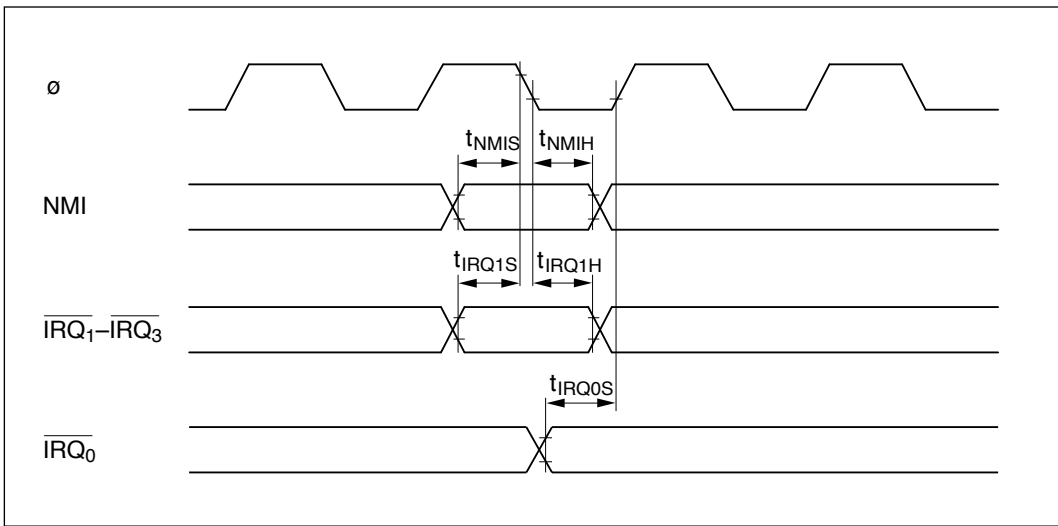

Figure 18-9 Interrupt Input Timing

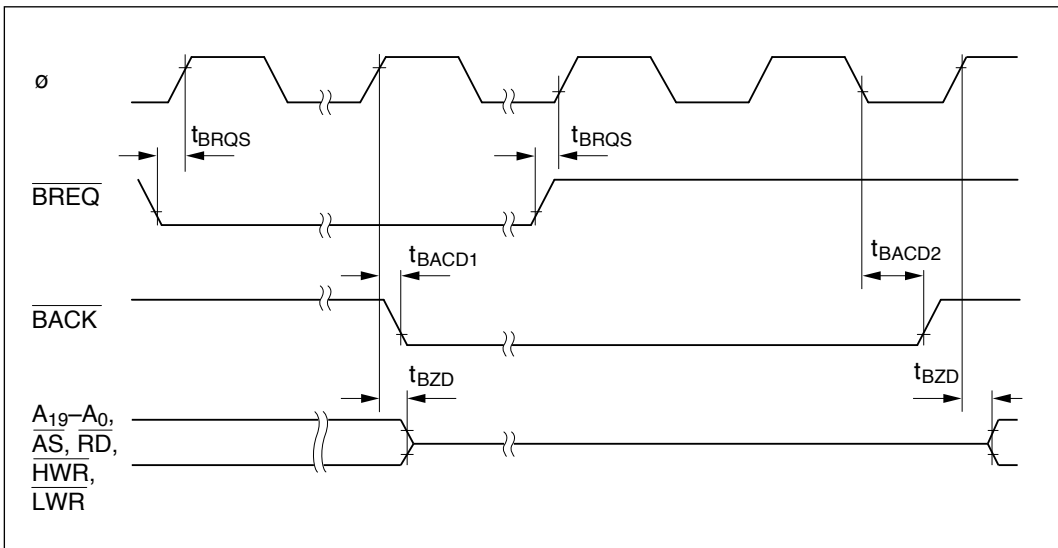

Figure 18-10 Bus-Release Mode Timing

18.3.3 Clock Timing

This section gives the following H8/538F clock timing diagram:

1. Oscillator settling timing

Figure 18-11 shows the oscillator settling timing.

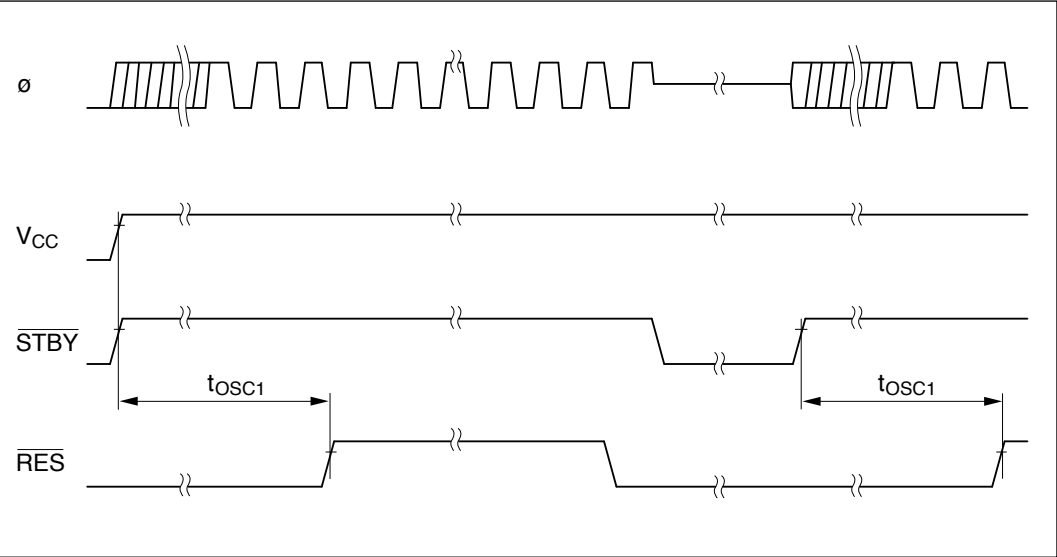

Figure 18-11 Oscillator Settling Timing

18.3.4 I/O Port Timing

This section gives the following H8/538F I/O port input/output timing diagram:

1. I/O port input/output timing

Figure 18-12 shows the I/O port input/output timing.

Figure 18-12 I/O Port Input/Output Timing

18.3.5 IPU Timing

This section gives the following H8/538F IPU timing diagrams:

1. IPU input/output timing

Figure 18-13 shows the IPU input/output timing.

2. IPU external clock input timing

Figure 18-14 shows the IPU external clock input timing.

Figure 18-13 IPU Input/Output Timing

Figure 18-14 IPU Clock Input Timing

18.3.6 SCI Input/Output Timing

This section gives the following H8/538F SCI timing diagrams:

1. SCI input clock timing

Figure 18-15 shows the SCI input clock timing.

2. SCI input/output timing (clocked synchronous mode)

Figure 18-16 shows the SCI input/output timing in clocked synchronous mode.

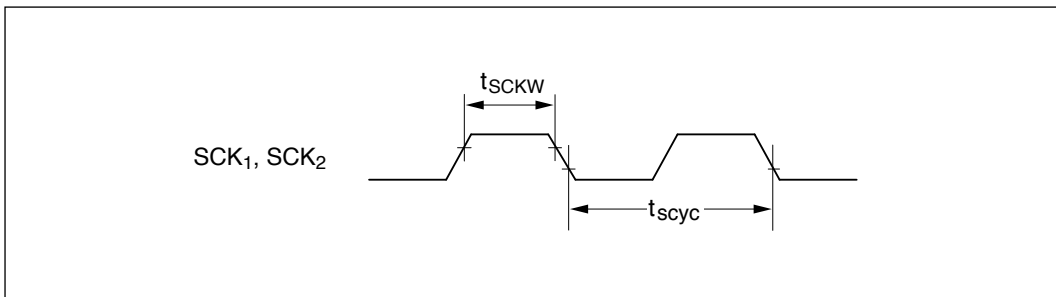

Figure 18-15 SCK Input Clock Timing

Figure 18-16 SCI Input/Output Timing

Appendix A Instruction Set

A.1 Instruction List

Operand Notation

Rd	General register (destination)
Rs	General register (source)
Rn	General register
(EAd)	Destination operand
(EAs)	Source operand
CCR	Condition code register
N	N (negative) bit in CCR
Z	Z (zero) bit in CCR
V	V (overflow) bit in CCR
C	C (carry) bit in CCR
CR	Control register
PC	Program counter
CP	Code page register
SP	Stack pointer
FP	Frame pointer
#IMM	Immediate data
disp	Displacement
+	Add
−	Subtract
×	Multiply
÷	Divide
^	Logical AND
v	Logical OR
⊕	Exclusive logical OR
→	Move
↔	Exchange
¬	Logical NOT

Condition Code Notation

↑	Changed according to execution result
0	Cleared to 0
—	Previous value remains unchanged
△	Varies depending on conditions

Mnemonic		Operation	Size	CCR Bits			
			B/W	N	Z	V	C
Data transfer instructions	MOV:G	(EAS) \rightarrow Rd Rs \rightarrow (EAd) #IMM \rightarrow (EAd)	B/W	\updownarrow	\updownarrow	0	—

Note: * Depends on the control register.

A.2 Machine-Language Instruction Codes

Tables A-1 (a) to (d) indicate the machine-language code for each instruction.

How to Read Tables A-1 (a) to (d): The general format consists of an effective address (EA) field followed by an operation code (OP) field.

Bytes 2, 3, 5, and 6 are not present in all instructions.

Instruction		Effective Address (EA) Field										Operation Code (OP) Field			
		Addressing Mode	1	2	3	10Szrrr	1101Szrrr	1110Szrrr	1111Szrrr	1011Szrrr	1100Szrrr				0000Sz101
		Rn	@ Rn	@ (d:8,Rn)	@ (d:16,Rn)	@ -Rn	@ Rn+	@ aa:8	@ aa:16	#xx:8	#xx:16	4	5	6	
Data transfer	MOV:G.B <EAs>,Rd	2	2	3	4	2	2	3	4	3	10000rdrdrd				
	MOV:G.W <EAs>,Rd	2	2	3	4	2	2	3	4	4	10000rdrdrd				
	MOV:G.B Rs,<EAd>		2	3	4	2	2	3	4		10010rsrsrs				
	MOV:G.W Rs,<EAd>		2	3	4	2	2	3	4		10010rsrsrs				
	MOV:G.B #xx:8,<EAd>		3	4	5	3	3	4	5		00000110	Data			
	MOV:G.W #xx:16,<EAd>		4	5	6	4	4	5	6		00000111	Data (high)	Data (low)		
	LDM.W @SP+, <register list>						2				00000010	Register list			

Effective address (EA) field

Operation code (OP) field

Shading indicates addressing modes that cannot be specified in the instruction.

Byte length of instruction

In special-format instructions the operation code field precedes the effective address field.

The following notation is used in the tables:

- Sz: operand size designation (byte or word)

Sz = 0: byte size

Sz = 1: word size

- rrr: general register number

rrr	Sz = 0 (byte)				Sz = 1 (word)	
	15	8	7	0	15	0
000	Not used		R0		R0	
001	Not used		R1		R1	
010	Not used		R2		R2	
011	Not used		R3		R3	
100	Not used		R4		R4	
101	Not used		R5		R5	
110	Not used		R6		R6	
111	Not used		R7		R7	

- ccc: control register number

ccc	Sz = 0 (byte)				Sz = 1 (word)	
000	(disallowed*)				15	0
					SR	
001	15	8	7	0	(disallowed*)	
	Not used		CCR			
010	(disallowed*)				(disallowed*)	
011	Not used		BR		(disallowed*)	
100	Not used		EP		(disallowed*)	
101	Not used		DP		(disallowed*)	
110	(disallowed*)				(disallowed*)	
111	Not used		TP		(disallowed*)	

Note: * Do not use combinations marked as disallowed, since they may cause incorrect operation.

- d: direction of transfer

d = 0: load

d = 1: store

- Register list: a byte in which bits indicate general registers as follows.

Bit	7	6	5	4	3	2	1	0
	R7	R6	R5	R4	R3	R2	R1	R0

- #VEC: four bits specifying a vector number from 0 to 15. These vector numbers designate vector addresses as follows:

#VEC	Vector Address	
	Minimum Mode	Maximum Mode
0	H'0020–H'0021	H'0040–H'0043
1	H'0022–H'0023	H'0044–H'0047
2	H'0024–H'0025	H'0048–H'004B
3	H'0026–H'0027	H'004C–H'004F
4	H'0028–H'0029	H'0050–H'0053
5	H'002A–H'002B	H'0054–H'0057
6	H'002C–H'002D	H'0058–H'005B
7	H'002E–H'002F	H'005C–H'005F
8	H'0030–H'0031	H'0060–H'0063
9	H'0032–H'0033	H'0064–H'0067
A	H'0034–H'0035	H'0068–H'006B
B	H'0036–H'0037	H'006C–H'006F
C	H'0038–H'0039	H'0070–H'0073
D	H'003A–H'003B	H'0074–H'0077
E	H'003C–H'003D	H'0078–H'007B
F	H'003E–H'003F	H'007C–H'007F

Examples of Machine-Language Instruction Codes

Example 1: ADD:G.B @R0, R1

	EA Field	OP Field	Remarks
Table A-1	1101Szrrr	00100rdrdrd	ADD:G.B @Rs, Rd instruction code
Instruction code	11010000	00100001	Sz = 0 (byte)
	H'D021		Rs = R0, Rd = R1

Example 2: ADD:G.W @H'11:8, R1

	EA Field		OP Field	Remarks
Table A-1	0000Sz101	00010001	00100rdrdrd	ADD:G.W @aa:8, Rd instruction code
Instruction code	00001101	00010001	00100001	Sz = 1 (word)
	H'0D1121			aa = H'11, Rd = R1

A.4 Number of States Required for Execution

Tables A-7 (1) to (6) indicate the number of states required to execute each instruction in each addressing mode. These tables are read as explained on the following pages. The values of I, J, and K are used to calculate the number of execution states when the instruction is fetched from an external address or an operand is written or read at an external address. Formulas for calculating the number of states are given next.

Formulas for Calculating Number of States Required for Execution: One state is one cycle of the system clock (ϕ). When $\phi = 10$ MHz, one state is 100 ns.

Instruction Fetch	Operand Read/Write	Formula	
On-chip memory*1	On-chip memory or general register, or no operand	(value in table A-7) + (value in table A-8)	
	On-chip supporting module or external memory*2	Byte	(value in table A-7) + (value in table A-8) + I
		Word	(value in table A-7) + (value in table A-8) + 2I
External memory*2	On-chip memory or general register, or no operand	(value in table A-7) + 2 (J + K)	
	On-chip supporting module or external memory*2	Byte	(value in table A-7) + I + 2 (J + K)
		Word	(value in table A-7) + 2 (I + J + K)

- Notes: 1. When an instruction is fetched from on-chip memory (on-chip ROM or RAM), the number of states required for execution varies by one or two depending on whether the instruction starts at an even or odd address. This difference should be noted when software is used for timing or in other cases in which the exact number of states needs to be known.
2. If wait states are inserted in access to external memory, add the necessary number of states.

How to Read Table A-7

J + K is the number of instruction fetches

I is the total number of bytes written or read when the operand is in memory

Instruction	I	J	K	Addressing Mode									
				Rn	@Rn	@(d:8,Rn)	@(d:16,Rn)	@-Rn	@Rn+	@aa:8	@aa:16	#xx:8	#xx:16
ADD.B	1	1	2	1	5	5	6	5	6	5	6	3	
ADD.W	2	1	2	5	5	6	5	6	5	6			4
ADD:Q.B	2	1	2	7	7	8	7	8	7	8			
ADD:Q.W	4	1	2	7	7	8	7	8	7	8			
DADD		2	4										

Shading in the I column indicates that the instruction cannot have a memory operand.

Shading in these columns indicates addressing modes that cannot be specified for the instruction.

Examples of Calculation of Number of States Required for Execution

Example 1: ADD:G.W @R0, R1 with instruction fetched from on-chip memory

Operand Read/Write	Start Address	Assembler Notation			Formula (Value in Table A-7) + [Value in Table A-8 (b)]	Execution States
		Address	Code	Mnemonic		
On-chip memory or general register	Even	H'0100	H'D821	ADD:G.W @R0,R1	5 + 1	6
	Odd	H'0101	H'D821	ADD:G.W @#R0,R1	5 + 0	5

Example 2: JSR @R0 with instruction fetched from on-chip memory

Branch Address	Assembler Notation			Formula (Value in Table A-7) + [Value in Table A-8 (a)]	Execution State
	Address	Code	Mnemonic		
Even	H'FC00	H'11D8	JSR @R0	9 + 0 + 2 × 2	13
Odd	H'FC01	H'11D8	JSR @R0	9 + 1 + 2 × 2	14

Example 3: ADD:G.W @R0, R1 with instruction fetched from external memory

Operand Read/Write	Assembler Notation			Formula (Value in Table A-7) + 2 (J + K)	Execution States
	Address	Code	Mnemonic		
On-chip memory or general register	H'9002	H'D821	ADD:G.W @R0,R1	$5 + 2 \times (1 + 1)$	9

Calculation of Number of States Required for Execution (H8/538F): One state is one cycle of the system clock (ϕ). When $\phi = 10$ MHz, one state is 100 ns.

Instruction Fetch	Operand Read/Write	Formula	
16-bit-bus, 2-state-access area	16-bit-bus, 2-state-access area or general register	$(\text{value in table A-7}) + (\text{value in table A-8})$	
	16-bit-bus, 3-state-access area	Byte	$(\text{value in table A-7}) + (\text{value in table A-8}) + 1$
		Word	$(\text{value in table A-7}) + (\text{value in table A-8}) + 1/2$
	8-bit-bus, 2-state-access area or on-chip supporting module	Byte	$(\text{value in table A-7}) + (\text{value in table A-8}) + 1$
		Word	$(\text{value in table A-7}) + (\text{value in table A-8}) + 21$
16-bit-bus, 3-state-access area	16-bit-bus, 2-state-access area or general register	$(\text{value in table A-7}) + (\text{value in table A-8}) + (J + K)/2$	
	16-bit-bus, 3-state-access area	Byte	$(\text{value in table A-7}) + (\text{value in table A-8}) + 1 + (J + K)/2$
		Word	$(\text{value in table A-7}) + (\text{value in table A-8}) + (1 + J + K)/2$
	8-bit-bus, 2-state-access area or on-chip supporting module	Byte	$(\text{value in table A-7}) + (\text{value in table A-8}) + 1 + (J + K)/2$
		Word	$(\text{value in table A-7}) + (\text{value in table A-8}) + 21 + (J + K)/2$

(continued on next page)

Instruction Fetch	Operand Read/Write	Formula	
8-bit-bus, 3-state-access area	16-bit-bus, 2-state-access area or general register		$(\text{value in table A-7}) + 2 + (J + K)$
	16-bit-bus, 3-state-access area	Byte	$(\text{value in table A-7}) + I + 2 (J + K)$
		Word	$(\text{value in table A-7}) + I/2 (J + K)$
	8-bit-bus, 2-state-access area or on-chip supporting module	Byte	$(\text{value in table A-7}) + I + 2 (J + K)$
		Word	$(\text{value in table A-7}) + 2 (I + J + K)$

- Notes:
1. When an instruction is fetched from the 16-bit-bus access area, the number of states differs by 1 or 2 depending on whether the instruction is stored at an even or odd address. This point should be noted in software timing routines and other situations in which the precise number of states must be known.
 2. If wait states or T_p states are inserted in access to the 3-state-access area, add the necessary number of states.
 3. When an instruction is fetched from the 16-bit-bus 3-state-access area, fractions in the term $(J + K)/2$ should be rounded up.

Examples of Calculation of Number of States Required for Execution

Example 1: Instruction fetched from 16-bit-bus, 2-state-access area

Operand Read/Write	Start Address	Assembler Notation			Formula (Value in Table A-7) + (Value in Table A-8)	Execution States
		Address	Code	Mnemonic		
16-bit-bus, 2-state- access area or general register	Even	H'0100	D821	ADD @R0,R1	$5 + 1$	6
	Odd	H'0101	D821	ADD @R0,R1	$5 + 0$	5

Example 2: Instruction fetched from 16-bit-bus, 2-state-access area

Operand Read/Write	Start Address	Assembler Notation			Formula (Value in Table A-7) + (Value in Table A-8) + 2I	Execution States
		Address	Code	Mnemonic		
On-chip supporting module or 8-bit-bus, 3-state- access area (word)	Even	H'FC00	11D8	JSR @R0	$9 + 0 + 2 \times 2$	13
	Odd	H'FC01	11D8	JSR @R0	$9 + 1 + 2 \times 2$	14

Example 3: Instruction fetched from 8-bit-bus, 3-state-access area

Operand Read/Write	Assembler Notation			Formula (Value in Table A-7) + 2 (J + K)	Execution States
	Address	Code	Mnemonic		
16-bit-bus, 2-state- access area or general register	H'9002	D821	ADD @R0,R1	$5 + 2 \times (1 + 1)$	9

Example 4: Instruction fetched from 16-bit-bus, 2-state-access area

Operand Read/Write	Start Address	Assembler Notation			Formula (Value in Table A-7) + (Value in Table A-8) + (J + K)/2	Execution States
		Address	Code	Mnemonic		
16-bit-bus, 2-state- access area or general register	Even	H'0100	D821	ADD @R0,R1	$5 + 1 + (1 + 1)/2$	7
	Odd	H'0101	D821	ADD @R0,R1	$5 + 0 + (1 + 1)/2$	6

A.5 Instruction Set

A.5.1 Features

Features of the H8/500 CPU instruction set are as follows:

- General-register architecture
- Highly orthogonal instruction set
- Supports register-register and register-memory operations
- Oriented toward C language

A.5.2 Instruction Types

The H8/500 CPU instruction set consists of 63 instructions. Table A-9 classifies the instruction set.

Table A-9 Instruction Types

Type	Instructions	Number of Instructions
Data transfer	MOV LDM STM XCH SWAP MOVTPE MOVFPE	7
Arithmetic operations	ADD SUB ADDS SUBS ADDX SUBX DADD DSUB MULXU DIVXU CMP EXTs EXTU TST NEG CLR TAS	17
Logic operations	AND OR XOR NOT	4
Shift	SHAL SHAR SHLL SHLR ROTL ROTR ROTXL ROTXR	8
Bit manipulation	BSET BCLR BTST BNOT	4
Branch	Bcc* JMP PJMP BSR JSR PJSR RTS PRTS RTD PRTD SCB(/F/NE/EQ)	11
System control	TRAPA TRAP/VS RTE SLEEP LDC STC ANDC ORC XORC NOP LINK UNLK	12

Note: * Bcc is the generic designation for a conditional branch instruction.

A.5.3 Basic Instruction Formats

(1) **General Format:** This format consists of an effective address (EA) field, an effective address extension field, and an operation code (OP) field. The effective address is placed before the operation code because this results in faster execution of the instruction. Table A-10 describes the three fields of the general instruction format.

Table A-10 Fields in General Instruction Format

Name	Byte Length	Description
EA field	1	Information used to calculate the effective address of an operand
EA extension	0–2	Byte length is defined in EA field Displacement value, immediate data, or absolute address
OP field	1–3	Defines the operation carried out on the operand Some instructions (DADD, DSUB, MOVFPE, MOVTPE) have an extended format in which the operand code is preceded by a one-byte prefix code (example 1)

Example 1: Instruction with prefix code: DADD instruction

(2) **Special Format:** In this format the operation code comes first, followed by the effective address field and effective address extension. This format is used in branching instructions, system control instructions, and some short-format instructions that can be executed faster if the operation is specified before the operand. Table A-11 describes the three fields of the special instruction format.

Table A-11 Fields in Special Instruction Format

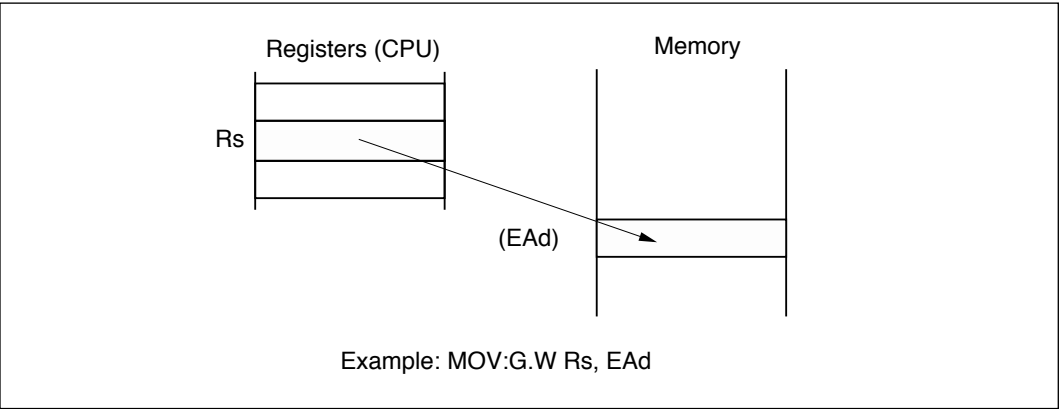

Name	Byte Length	Description
OP field	1–2	Defines the operation performed by the instruction
EA field and EA extension	0–3	Information used to calculate an effective address

A.5.4 Data Transfer Instructions

There are seven data transfer instructions. The function of each instruction is described next.

(1) MOV Instruction: Transfers data between two general registers, or between a general register and memory. Can also transfer immediate data to a register or memory.

Operation: (EAs) → (EAd),
#IMM → (EAd)

Instructions and Operand Sizes: The following table lists the possible combinations.

Instruction	Size		
	B/W	B	W
MOV:G	○		
MOV:E		○	
MOV:F	○		
MOV:I			○
MOV:L	○		
MOV:S	○		

B: Byte
W: Word

(2) LDM Instruction (W): Loads data saved on the stack into one or more registers. Multiple registers can be loaded simultaneously.

Operation: @SP+ (stack) → Rn (register list)

Example: LDM R0–R2, @SP+

Instructions and Operand Sizes: The operand size is always word size.

(3) STM Instruction (W): Saves data onto the stack. Multiple registers can be saved simultaneously.

Operation: Rn (register list) → @–SP (stack)

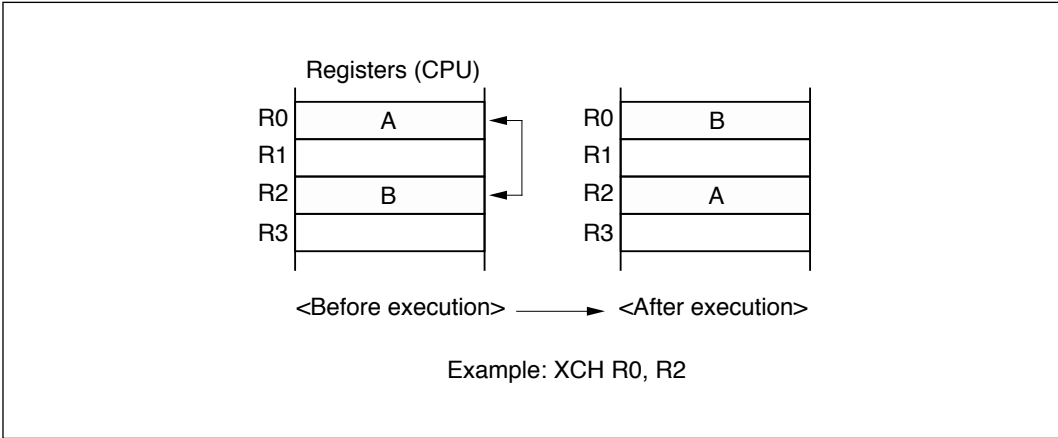

Example: STM @–SP, R0–R2

Instructions and Operand Sizes: The operand size is always word size.

(4) XCH Instruction (W): Exchanges data between two general registers.

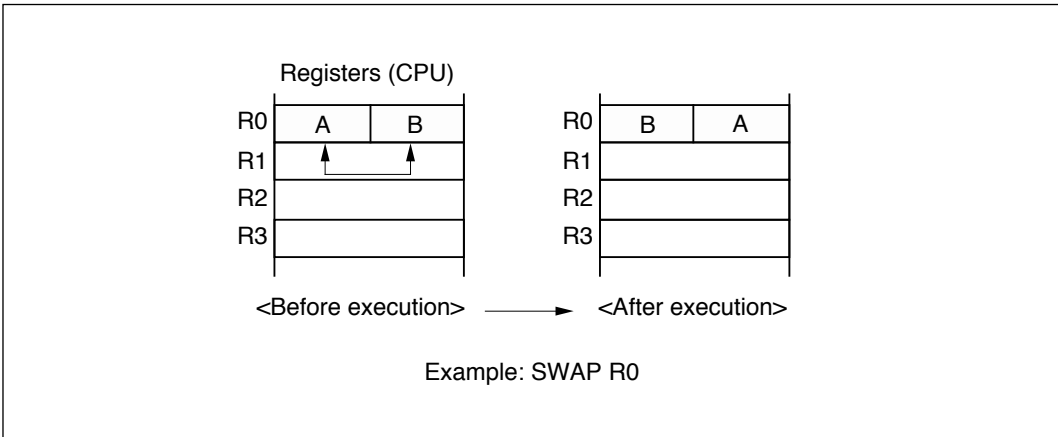

Operation: $R_s \rightarrow R_d, R_d \rightarrow R_s$

Instructions and Operand Sizes: The operand size is always word size.

(5) SWAP Instruction (W): Exchanges data between the upper and lower bytes of a general register.

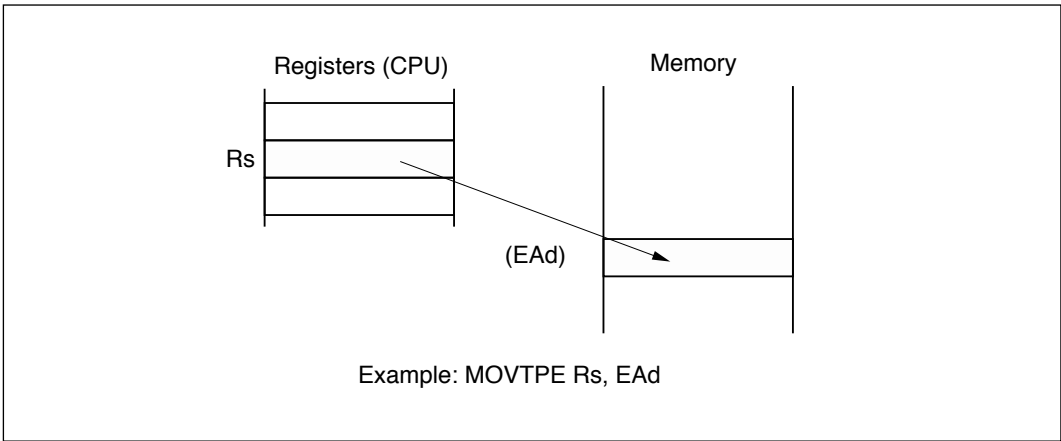

Operation: $R_d \text{ (upper byte)} \leftrightarrow R_d \text{ (lower byte)}$

Instructions and Operand Sizes: The operand size is always byte size.

(6) MOVTPE Instruction (B): Transfers general register contents to memory in synchronization with the E clock. (Note: The H8/538F does not output an E clock).

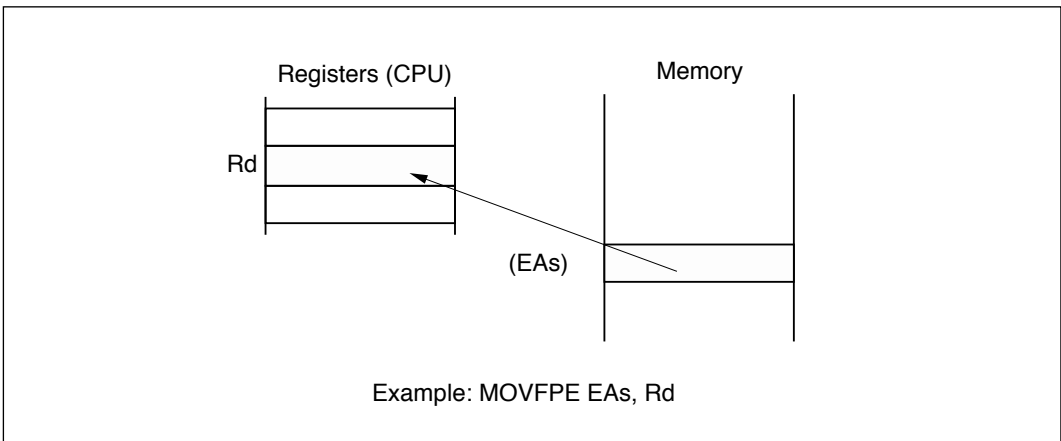

Operation: $R_n \rightarrow (EAd)$

Instructions and Operand Sizes: The operand size is always byte size.

(7) MOVFPE Instruction (B): Transfers memory contents to a general register in synchronization with the E clock. (Note: The H8/538F does not output an E clock).

Operation: $(EAs) \rightarrow R_d$

Instructions and Operand Sizes: The operand size is always byte size.

A.5.5 Arithmetic Instructions

There are 17 arithmetic instructions. The function of each instruction is described next.

(1) **ADD Instruction (B/W)**

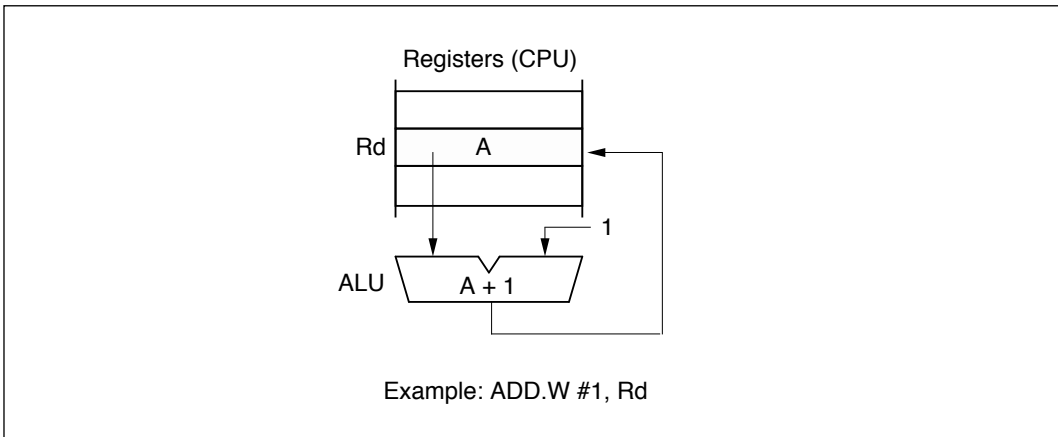

(2) **SUB Instruction (B/W)**

(3) **ADDS Instruction (B/W)**

(4) **SUBS Instruction (B/W)**

These instructions perform addition and subtraction on data in two general registers, data in a general register and memory, data in a general register and immediate data, or data in memory and immediate data.

Operation: $Rd \pm (EAs) \rightarrow Rd$, $(EAd) \pm \#IMM \rightarrow (EAd)$

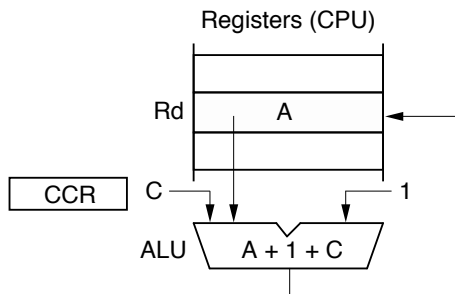

Instructions and Operand Sizes: Byte or word operand size can be selected.

(5) **ADDX Instruction (B/W)**

(6) **SUBX Instruction (B/W)**

These instructions perform addition and subtraction with carry on data in two general registers, data in a general register and memory, or data in a general register and immediate data.

Operation: $Rd \pm (EAs) \pm C \rightarrow Rd$

Example: ADDX.W #1, Rd

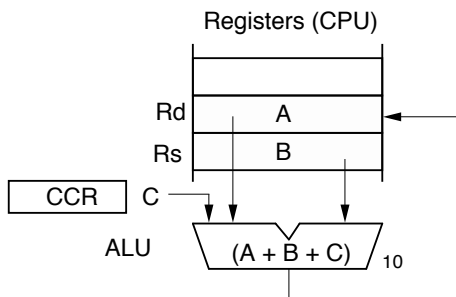

Instructions and Operand Sizes: Byte or word operand size can be selected.

(7) **DADD Instruction (B)**

(8) **DSUB Instruction (B)**

These instructions perform decimal addition and subtraction on data in two general registers.

Operation: $(Rd)_{10} \pm (Rs)_{10} \pm C \rightarrow (Rd)_{10}$

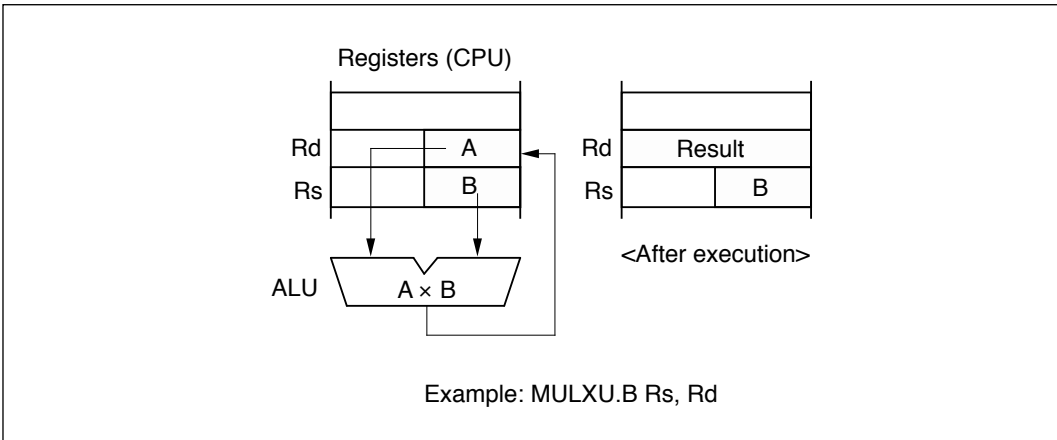

Example: DADD Rs, Rd

Instructions and Operand Sizes: The operand size is always byte size.

(9) MULXU Instruction (B/W): Performs 8-bit × 8-bit or 16-bit × 16-bit unsigned multiplication on data in a general register and data in another general register or memory, or on data in a general register and immediate data.

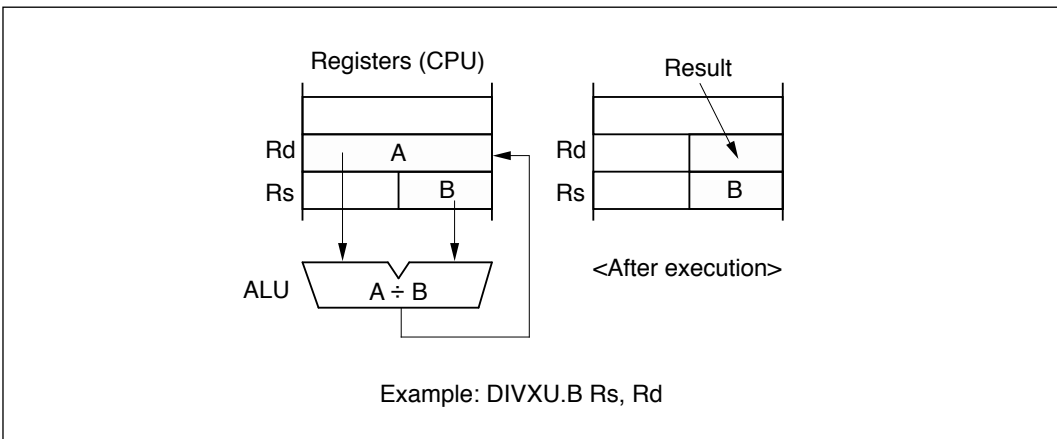

Operation: $Rd \times (EAs) \rightarrow Rd$

Instructions and Operand Sizes: Byte or word operand size can be selected.

(10) DIVXU Instruction (B/W): Performs 16-bit ÷ 8-bit or 32-bit ÷ 16-bit unsigned division on data in a general register and data in another general register or memory, or on data in a general register and immediate data.

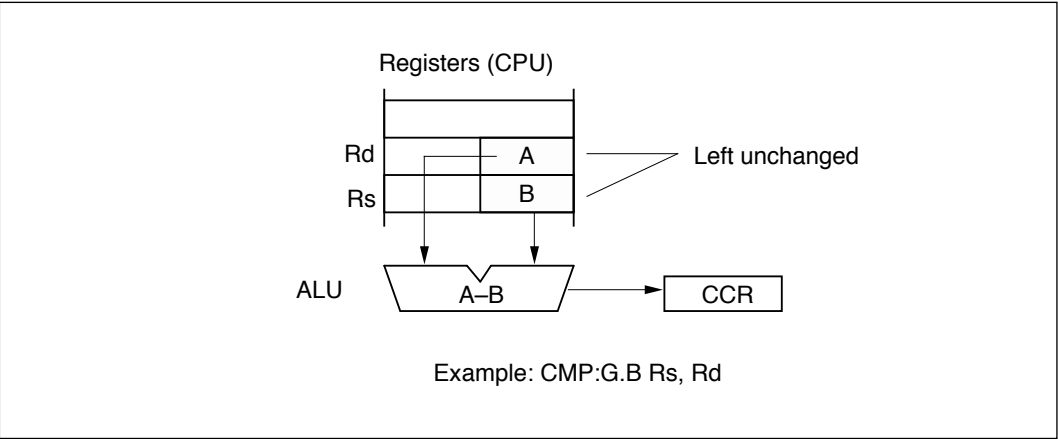

Operation: $Rd \div (EAs) \rightarrow Rd$

Instructions and Operand Sizes: Byte or word operand size can be selected.

(11) CMP Instruction: Compares data in a general register with data in another general register or memory, or with immediate data, or compares immediate data with data in memory.

Operation: $Rd - (EAs), (EAd) - \#IMM$

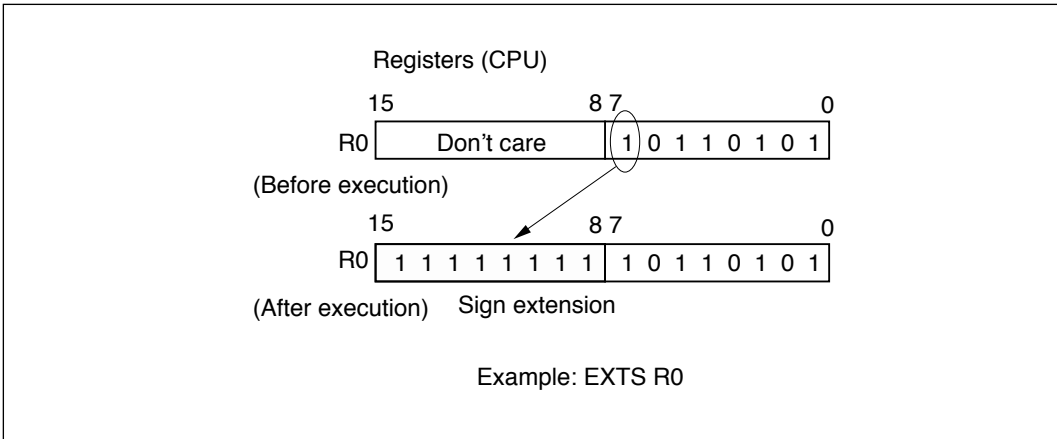

Instructions and Operand Sizes: The following table lists the possible combinations.

Instruction	Size		
	B/W	B	W
CMP:G	○		
CMP:E		○	
CMP:I			○

B: Byte
W: Word

(12) EXTS Instruction (B): Converts byte data in a general register to word data by extending the sign bit.

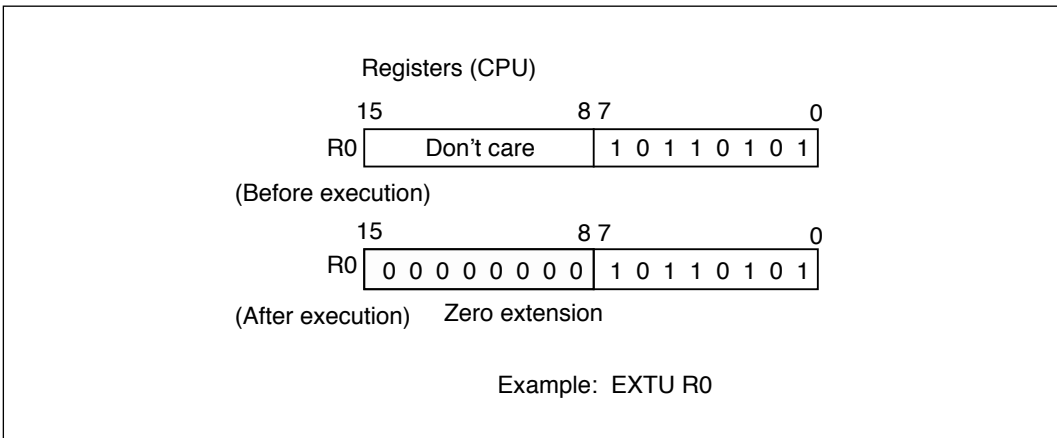

Operation: (<bit 7> of <Rd>) → (<bits 15 to 8> of <Rd>)

Instructions and Operand Sizes: The operand size is always byte size.

(13) EXTU Instruction (B): Converts byte data in a general register to word data by padding with zero bits.

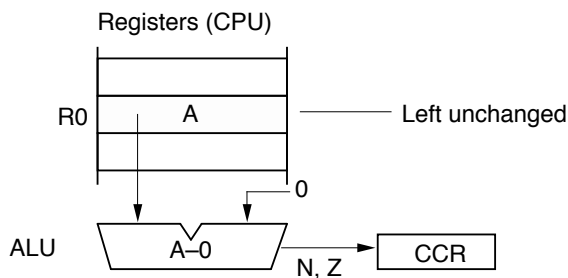

Operation: 0 → (<bits 15 to 8> of <Rd>)

Instructions and Operand Sizes: The operand size is always byte size.

(14) TST Instruction (B/W): Compares general register or memory contents with zero.

Operation: (EAd) – 0

Example: TST.W R0

Instructions and Operand Sizes: Byte or word operand size can be selected.

(15) NEG Instruction (B/W): Obtains the two's complement of general register or memory contents.

Operation: 0 – (EAd) → (EAd)

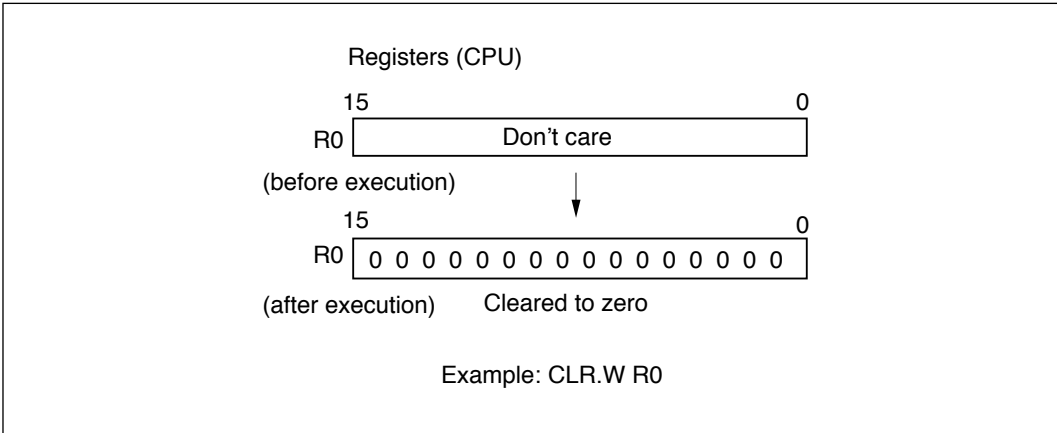

Example: NEG.W R0

Instructions and Operand Sizes: Byte or word operand size can be selected.

(16) CLR Instruction (B/W): Clears general register or memory contents to zero.

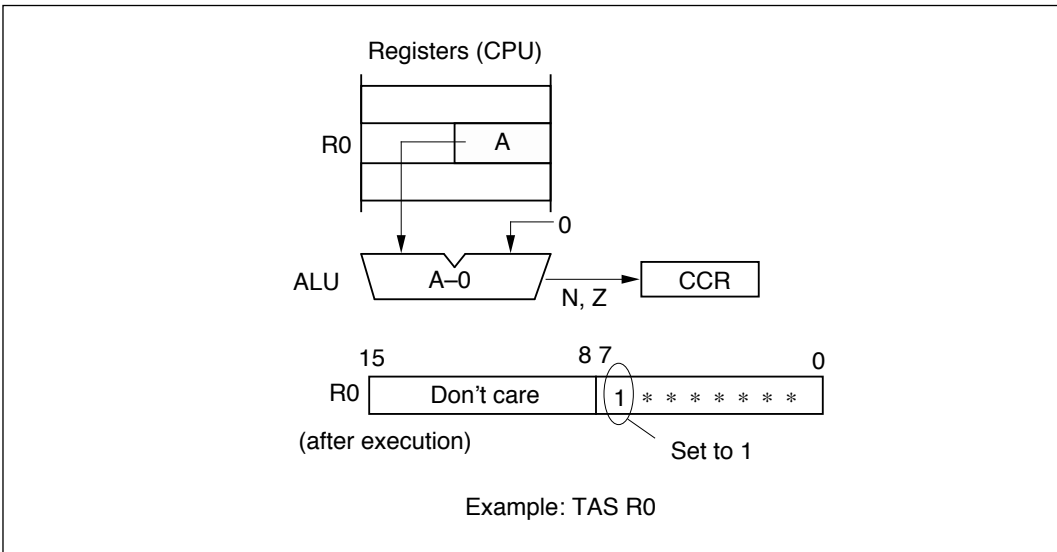

Operation: $0 \rightarrow (\text{EAd})$

Instructions and Operand Sizes: Byte or word operand size can be selected.

(17) TAS Instruction (B): Tests general register or memory contents, then sets the most significant bit (bit 7) to 1.

Operation: $(\text{EAd}) - 0, (1)_2 \rightarrow (<\text{bit } 7> \text{ of } <\text{EAd}>)$

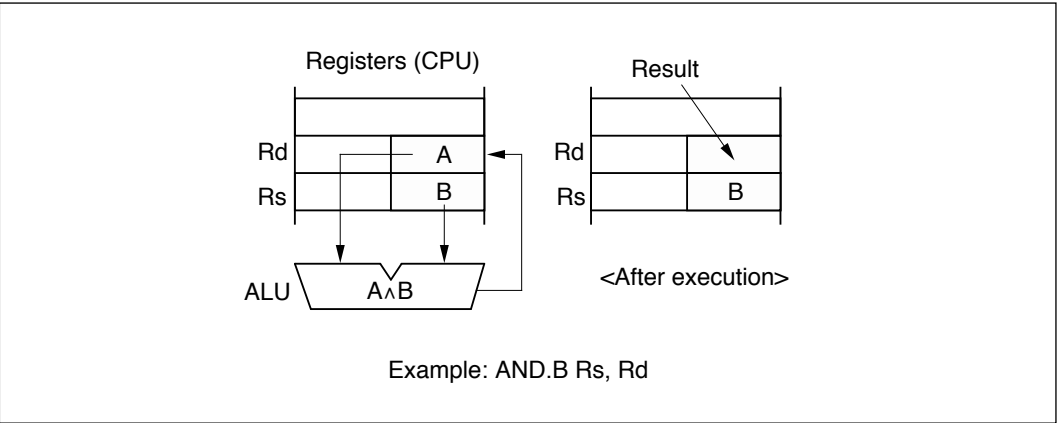

Instructions and Operand Sizes: The operand size is always byte size.

A.5.6 Logic Instructions

There are four logic instructions. The function of each instruction is described next.

(1) AND Instruction (B/W): Performs a logical AND operation on a general register and another general register, memory, or immediate data.

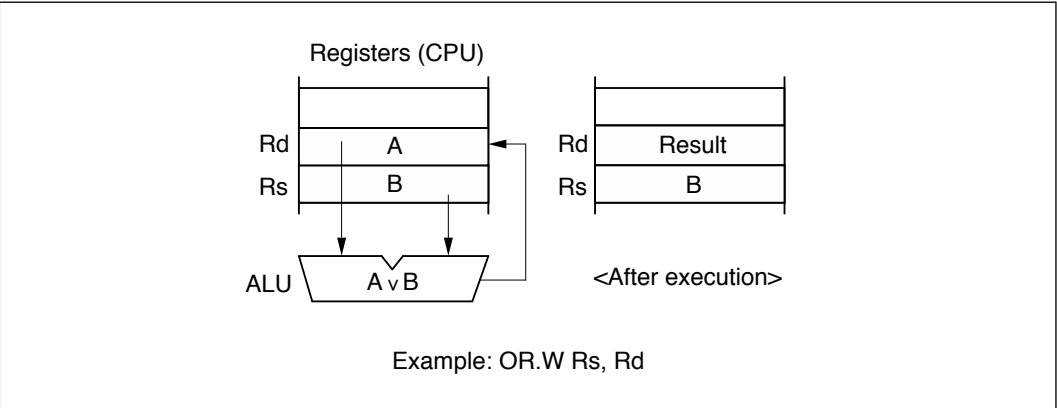

Operation: $Rd \wedge (EAs) \rightarrow Rd$

Instructions and Operand Sizes: Byte or word operand size can be selected.

(2) OR Instruction (B/W): Performs a logical OR operation on a general register and another general register, memory, or immediate data.

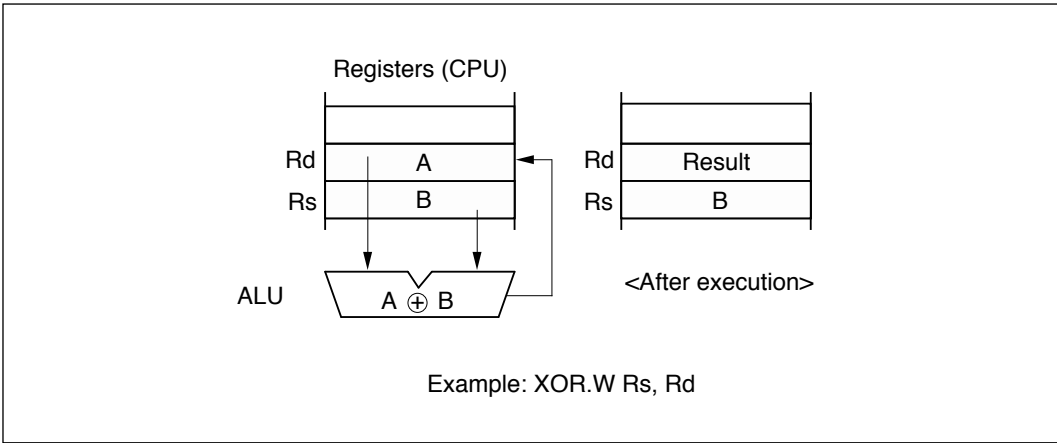

Operation: $Rd \vee (EAs) \rightarrow Rd$

Instructions and Operand Sizes: Byte or word operand size can be selected.

(3) XOR Instruction (B/W): Performs a logical exclusive OR operation on a general register and another general register, memory, or immediate data.

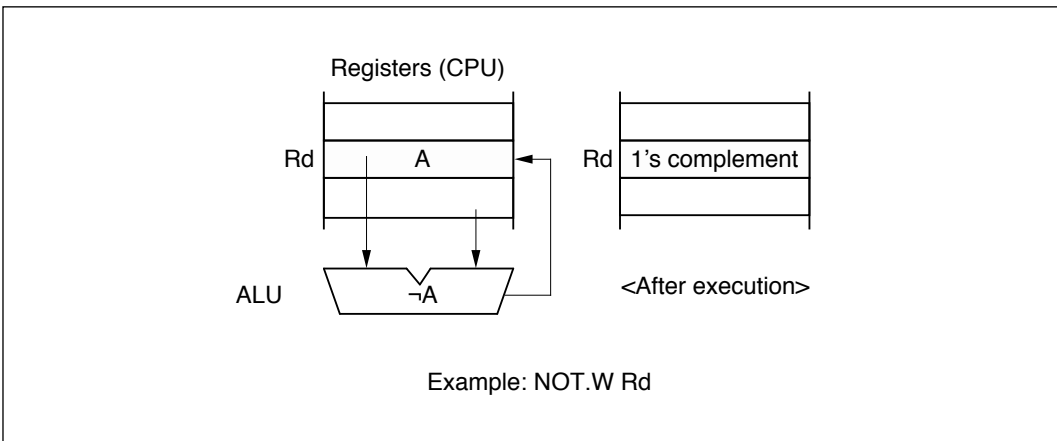

Operation: $Rd \oplus (EAs) \rightarrow Rd$

Instructions and Operand Sizes: Byte or word operand size can be selected.

(4) NOT Instruction (B/W): Takes the one's complement of general register or memory contents.

Operation: $\neg (EAd) \rightarrow (EAd)$

Instructions and Operand Sizes: Byte or word operand size can be selected.

A.5.7 Shift Instructions

There are eight shift instructions. The function of each instruction is described next.

(1) SHAL Instruction (B/W)

(2) SHAR Instruction (B/W)

These instructions perform an arithmetic shift operation on general register or memory contents.

Operation: (EAd) arithmetic shift \rightarrow (EAd)

Instructions and Operand Sizes: Byte or word operand size can be selected.

(3) SHLL Instruction (B/W)

(4) SHLR Instruction (B/W)

These instructions perform a logic shift operation on general register or memory contents.

Operation: (EAd) logic shift \rightarrow (EAd)

Instructions and Operand Sizes: Byte or word operand size can be selected.

(5) ROTL Instruction (B/W)

(6) ROTR Instruction (B/W)

These instructions rotate general register or memory contents.

Operation: (EAd) rotate \rightarrow (EAd)

Instructions and Operand Sizes: Byte or word operand size can be selected.

(7) ROTXL Instruction (B/W)

(8) ROTXR Instruction (B/W)

These instructions rotate general register or memory contents through the carry bit.

Operation: (EAd) rotate through carry \rightarrow (EAd)

Example: ROTXL.W Rd

Example: ROTXR.W Rd

Instructions and Operand Sizes: Byte or word operand size can be selected.

A.5.8 Bit Manipulation Instructions

There are four bit manipulation instructions. The function of each instruction is described next.

(1) BSET Instruction (B/W): Tests a specified bit in a general register or memory, then sets the bit to 1. The bit is specified by immediate data or a bit number in a general register.

Operation: $\neg(\text{<bit-No.> of <EAd>}) \rightarrow Z$
 $1 \rightarrow (\text{<bit-No.> of <EAd>})$

Example: BSET.W H'E, R1

Instructions and Operand Sizes: Byte or word operand size can be selected.

(2) BCLR Instruction (B/W): Tests a specified bit in a general register or memory, then clears the bit to 0. The bit is specified by immediate data or a bit number in a general register.

Operation: $\neg(\text{<bit-No.> of <EAd>}) \rightarrow Z$
 $0 \rightarrow (\text{<bit-No.> of <EAd>})$

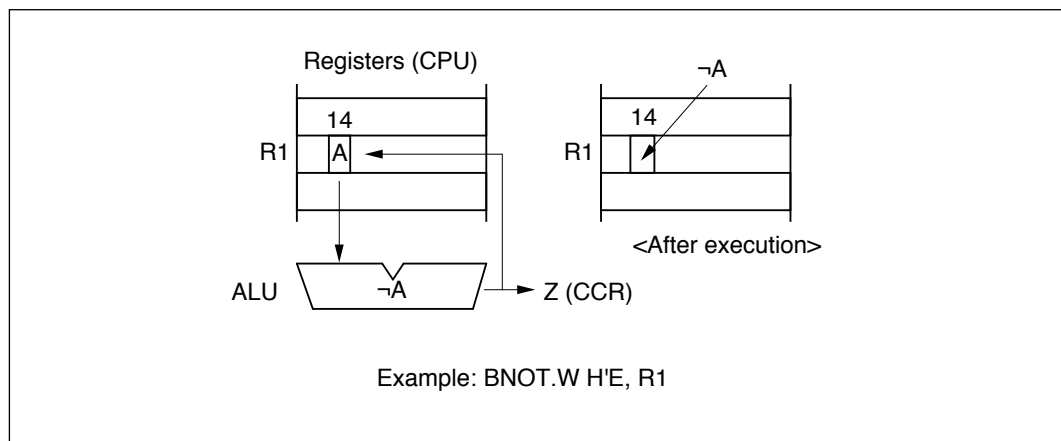

Example: BCLR.W H'E, R1

Instructions and Operand Sizes: Byte or word operand size can be selected.

(3) BNOT Instruction (B/W): Tests a specified bit in a general register or memory, then inverts the bit. The bit is specified by immediate data or a bit number in a general register.

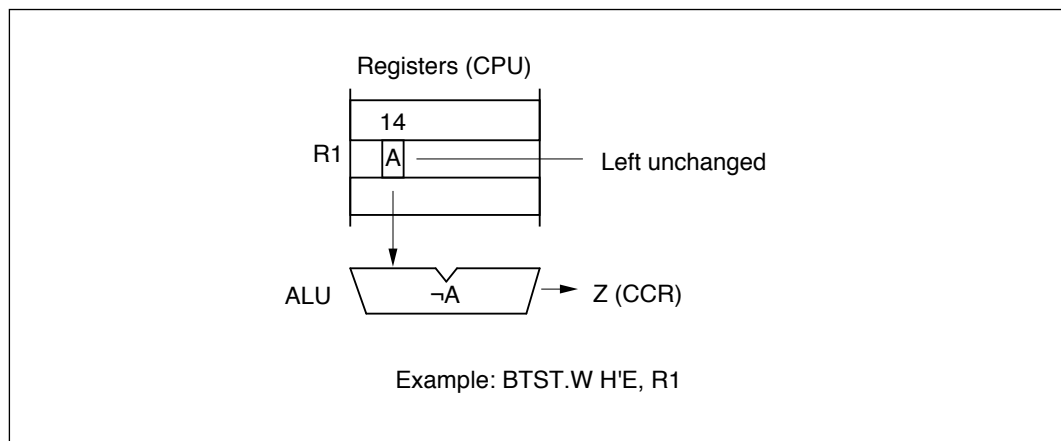

Operation: $\neg(\text{<bit-No.> of <EAd>}) \rightarrow Z \rightarrow (\text{<bit-No.> of <EAd>})$

Instructions and Operand Sizes: Byte or word operand size can be selected.

(4) BTST Instruction (B/W): Tests a specified bit in a general register or memory. The bit is specified by immediate data or a bit number in a general register.

Operation: $\neg(\text{<bit-No.> of <EAd>}) \rightarrow Z$

Instructions and Operand Sizes: Byte or word operand size can be selected.

A.5.9 Branch Instructions

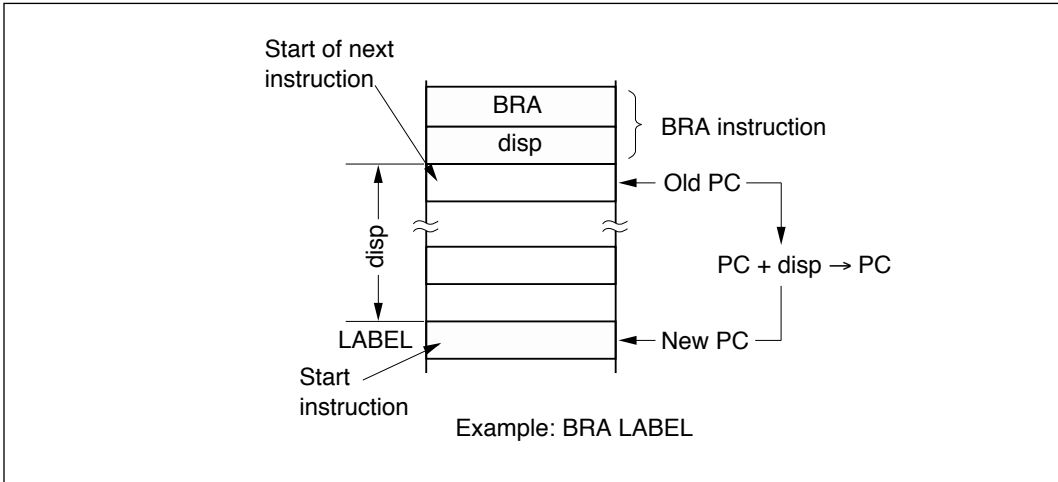

There are 11 branch instructions. The function of each instruction is described next.

(1) **Bcc Instruction (—):** Branches if the condition specified in the instruction is true.

Operation: If condition is true then

$PC + \text{disp} \rightarrow PC$

else next;

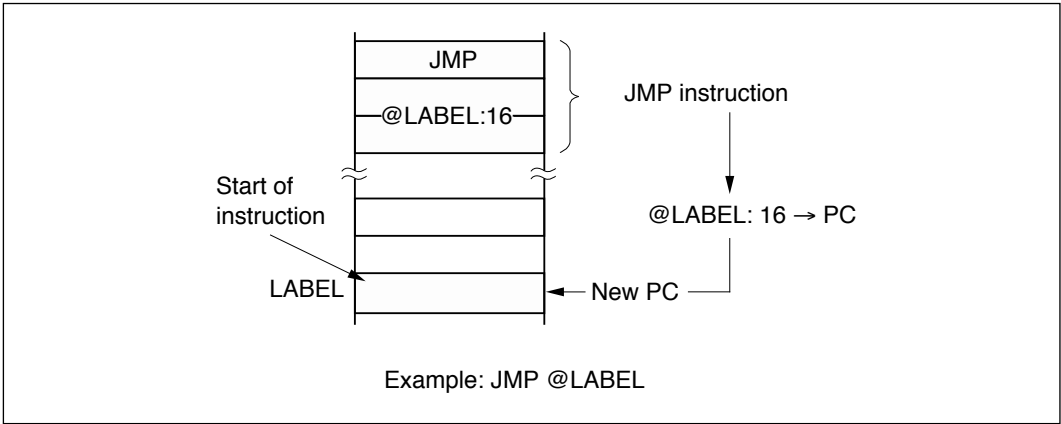

Note: This instruction cannot branch across a page boundary.

Addressing of Branch Destination: Specified by an eight-bit or 16-bit displacement.

Mnemonic	Description	Condition
BRA (BT)	Always (true)	True
BRN (BF)	Never (false)	False
BHI	High	$C \vee Z = 0$
BLS	Low or same	$C \vee Z = 1$
BCC (BHS)	Carry clear (high or same)	$C = 0$
BCS (BLO)	Carry set (low)	$C = 1$
BNE	Not equal	$Z = 0$
BEQ	Equal	$Z = 1$
BVC	Overflow clear	$V = 0$
BVS	Overflow set	$V = 1$
BPL	Plus	$N = 0$
BMI	Minus	$N = 1$
BGE	Greater or equal	$N \oplus V = 0$
BLT	Less than	$N \oplus V = 1$
BGT	Greater than	$Z \vee (N \oplus V) = 0$
BLE	Less or equal	$Z \vee (N \oplus V) = 1$

(2) JMP Instruction (—): Branches unconditionally to a specified address in the same page.

Operation: <EA> → PC

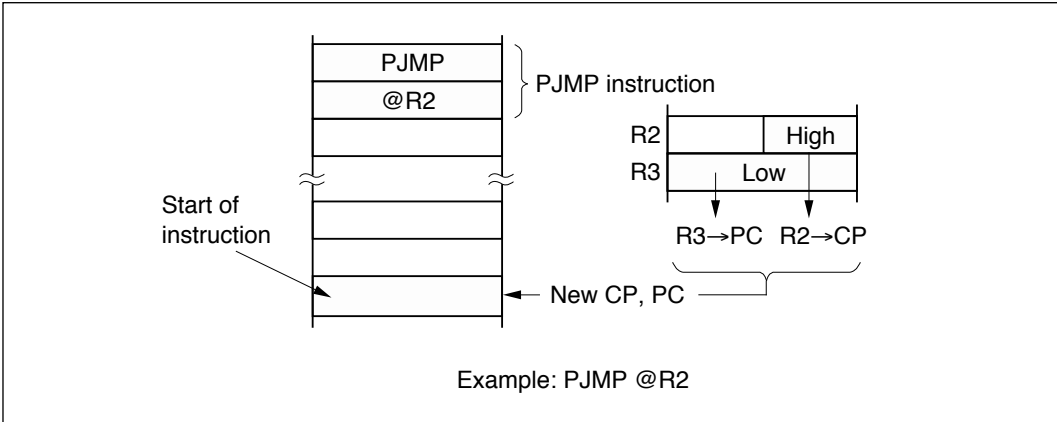

Addressing of Branch Destination: Register indirect, register indirect with eight-bit or 16-bit displacement, or 16-bit direct addressing.

Note: This instruction cannot branch across a page boundary.

(3) PJMP Instruction (—): Branches unconditionally to a specified address in a specified page.

Operation: $\langle EA \rangle \rightarrow CP, PC$

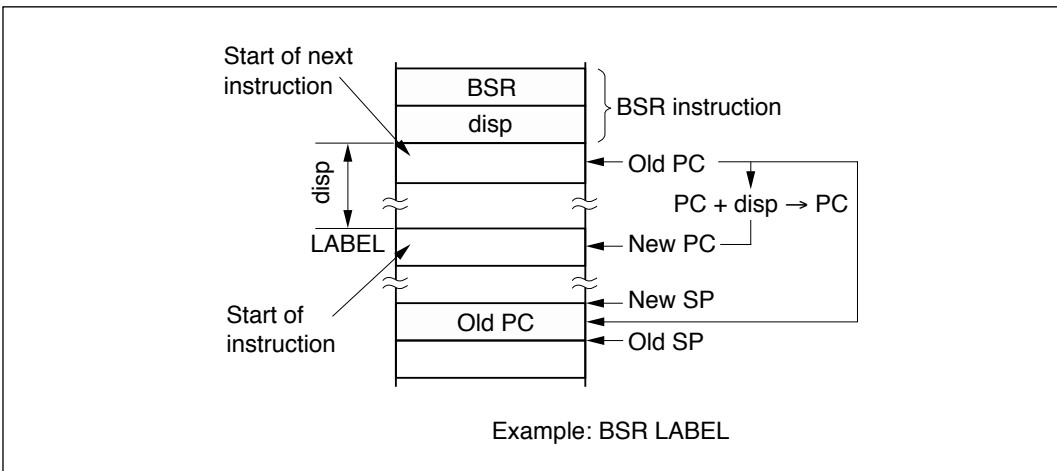

Addressing of Branch Destination: Register indirect or 24-bit direct addressing.

Note: This instruction is invalid in minimum mode.

(4) BSR Instruction (—): Branches to a subroutine at a specified address in the same page.

Operation: $PC \rightarrow @-SP, PC + disp \rightarrow PC$

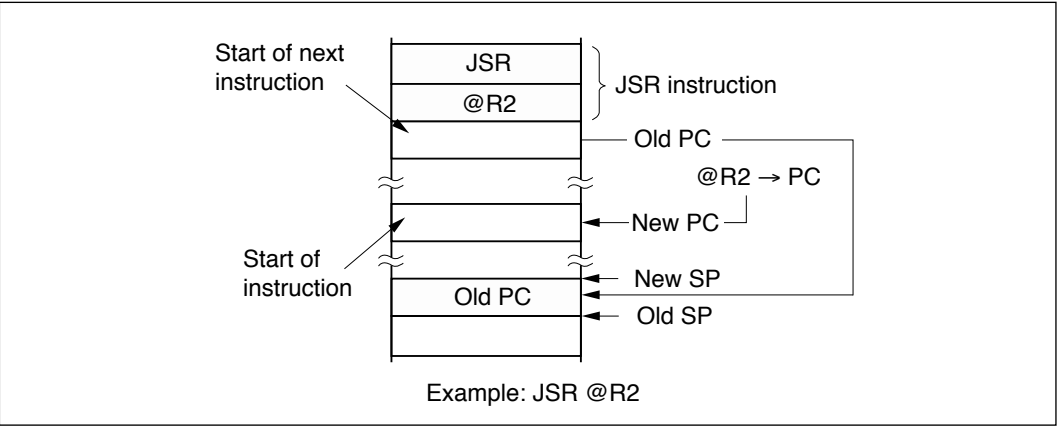

Addressing of Branch Destination: Specified by an eight-bit or 16-bit displacement.

Note: This instruction cannot branch across a page boundary.

(5) **JSR Instruction (—):** Branches to a subroutine at a specified address in the same page.

Operation: $PC \rightarrow @-SP, <EA> \rightarrow PC$

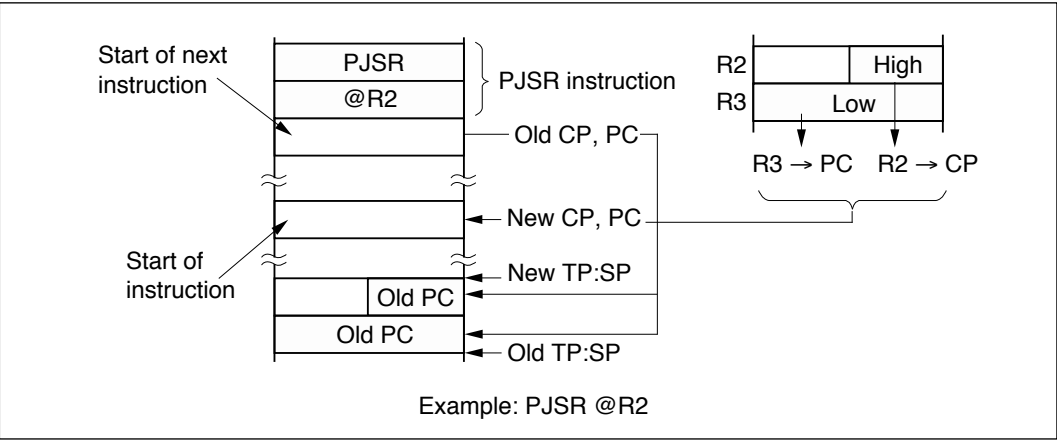

Addressing of Branch Destination: Register indirect, register indirect with eight-bit or 16-bit displacement, or 16-bit direct addressing.

Note: This instruction cannot branch across a page boundary.

(6) **PJSR Instruction (—):** Branches to a subroutine at a specified address in a specified page.

Operation: $PC \rightarrow @-SP, CP \rightarrow @-SP, <EA> \rightarrow PC$

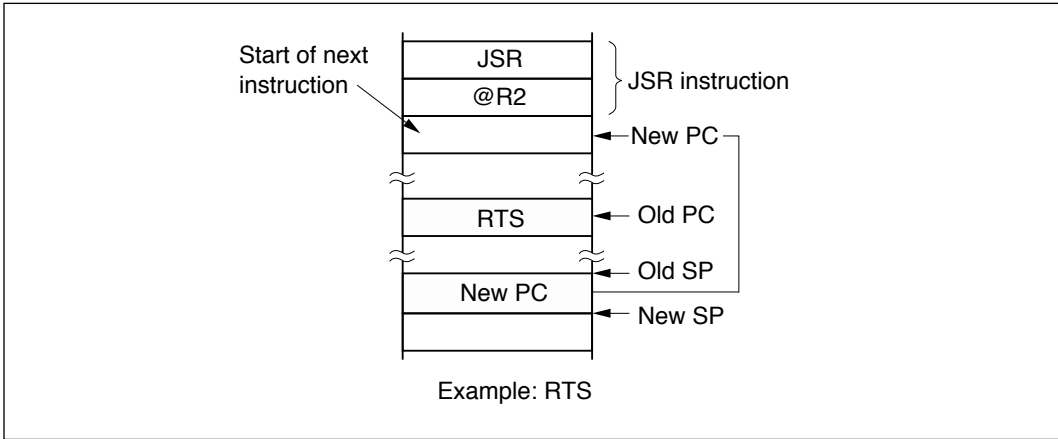

Addressing of Branch Destination: Register indirect or 24-bit direct addressing.

Note: This instruction is invalid in minimum mode.

(7) RTS Instruction (—): Returns from a subroutine in the same page.

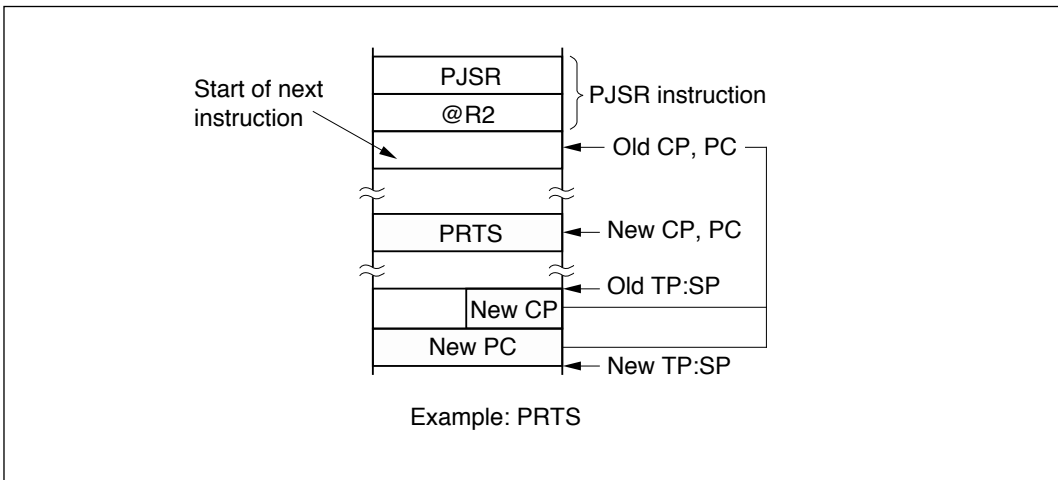

Operation: @SP+ → PC

RTS can return from a subroutine called by a BSR or JSR instruction.

(8) PRTS Instruction (—): Returns from a subroutine in another page.

Operation: @SP+ → PC, @SP+ → CP

PRTS can return from a subroutine called by a PJSR instruction.

(9) RTD Instruction (—): Returns from a subroutine in the same page and adjusts the stack pointer.

Operation: $@SP+ \rightarrow PC$, $SP + \#IMM \rightarrow SP$

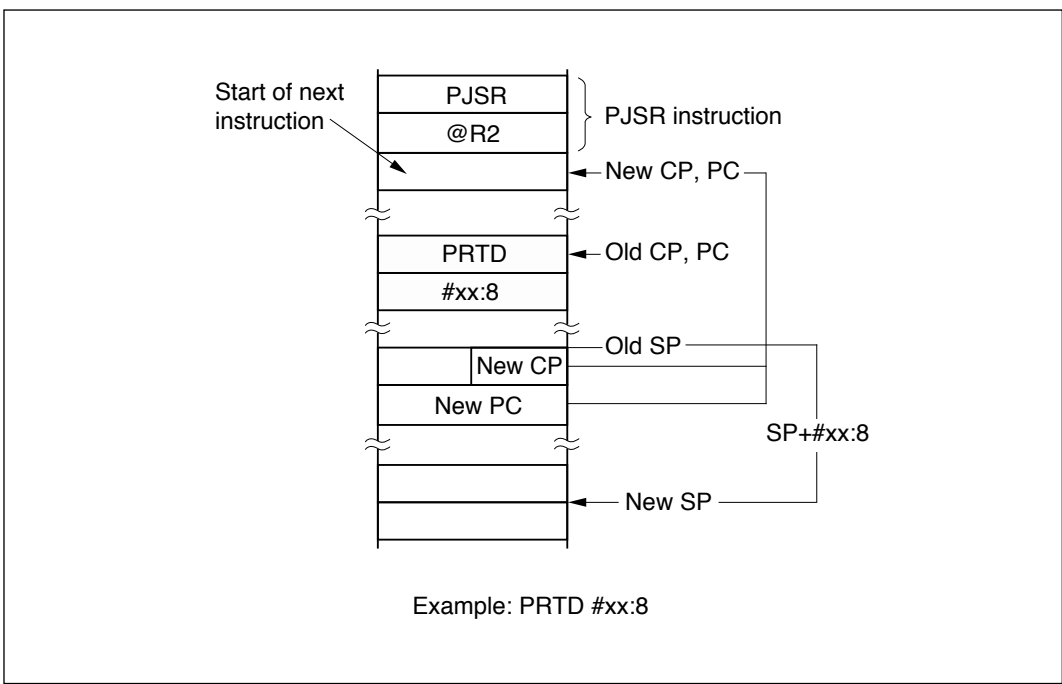

Example: RTD #xx:8

RTD can return from a subroutine called by a BSR or JSR instruction. The stack-pointer adjustment is specified by eight-bit or 16-bit immediate data.

Note: The immediate data must have an even value. If the stack pointer is set to an odd address, an address error will occur when the stack is accessed.

(10) PRTD Instruction (—): Returns from a subroutine in another page and adjusts the stack pointer.

Operation: $@SP+ \rightarrow PC$, $@SP+ \rightarrow CP$, $SP + \#IMM \rightarrow SP$

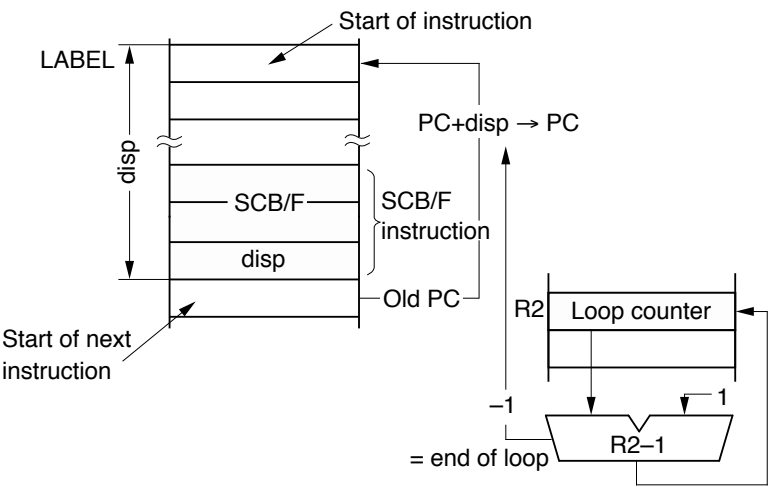

PRTD can return from a subroutine called by a PJSR instruction. The stack-pointer adjustment is specified by eight-bit or 16-bit immediate data.

Note: The immediate data must have an even value. If the stack pointer is set to an odd address, an address error will occur when the stack is accessed.

(11) SCB Instruction: Controls a loop using a loop counter and/or a specified termination condition.

Operation: If condition is true then next
 else $R_n - 1 \rightarrow R_n$;
If $R_n = -1$ then next
 else $PC + disp \rightarrow PC$;

Example: SCB/F R2, LABEL

Addressing of Branch Destination: Specified by an eight-bit displacement.

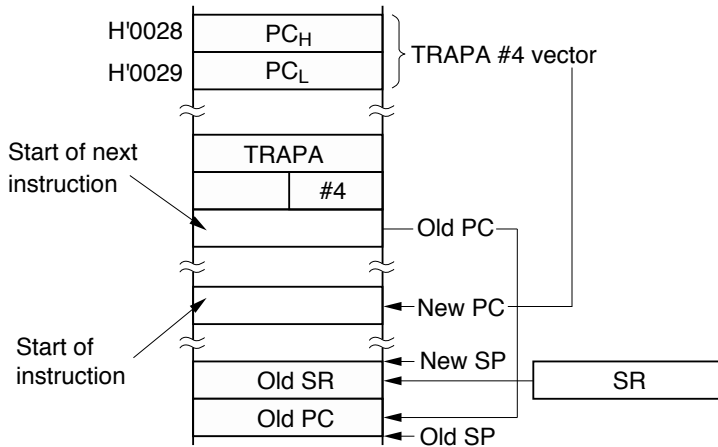

Instruction	Description	
	Function	Condition
SCB/F	False	—
SCB/NE	Not Equal	$Z = 0$
SCB/EQ	Equal	$Z = 1$

A.5.10 System Control Instructions

There are 12 system control instructions. The function of each instruction is described next.

(1) **TRAPA Instruction (—):** Generates a trap exception with a specified vector number.

Operation: $PC \rightarrow @-SP$, (maximum mode: $CP \rightarrow @-SP$), $SR \rightarrow @-SP$
 $\langle \text{vector} \rangle \rightarrow PC$ (maximum mode: $\langle \text{vector} \rangle \rightarrow CP$)

Example: TRAPA #4

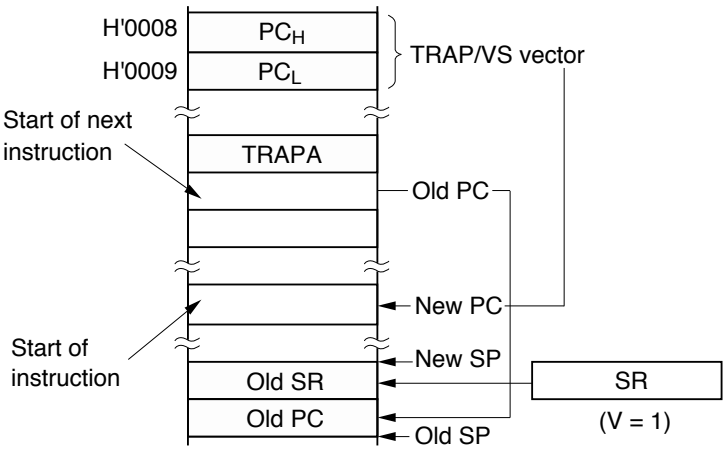

(2) **TRAP/VS Instruction (—):** Generates a trap exception if the V bit is set to 1.

Operation: If V bit of CCR = 1 then

PC → @-SP, (maximum mode: CP → @-SP), SR → @-SP

<vector> → PC (maximum mode: <vector> → CP)

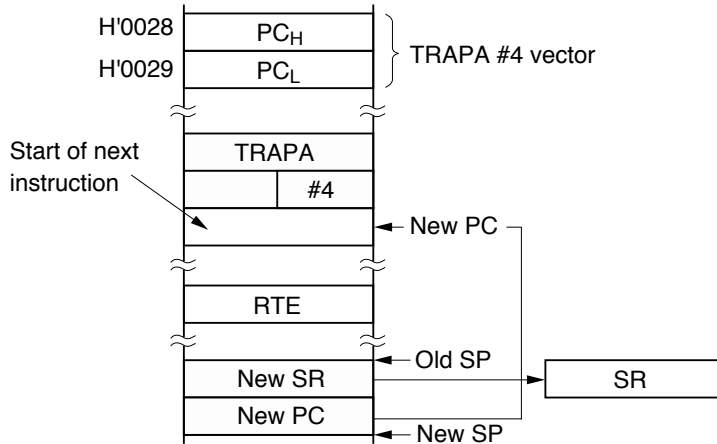

else next;

Example: TRAP/VS

(3) RTE Instruction (—): Returns from an exception-handling routine.

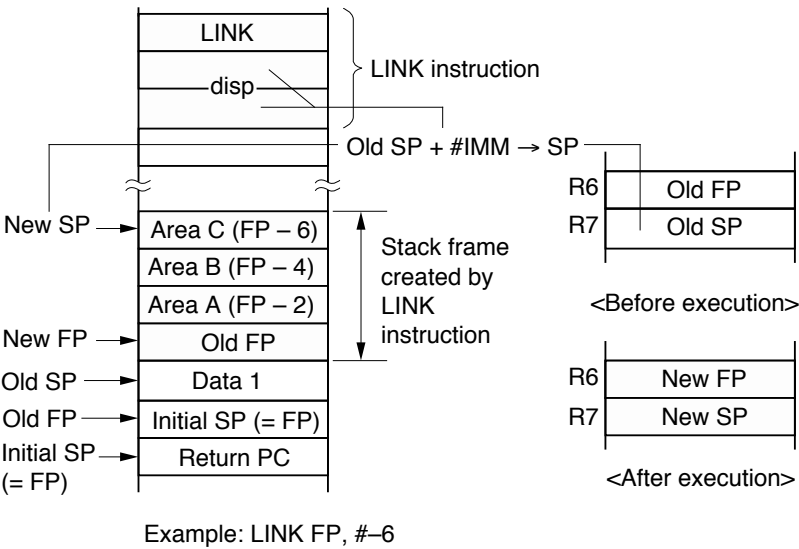

Operation: $@SP+ \rightarrow PC$,
(maximum mode: $@SP+ \rightarrow CP$),
 $@SP+ \rightarrow SR$

Example: RTE

(4) **LINK Instruction (—):** Creates a stack frame.

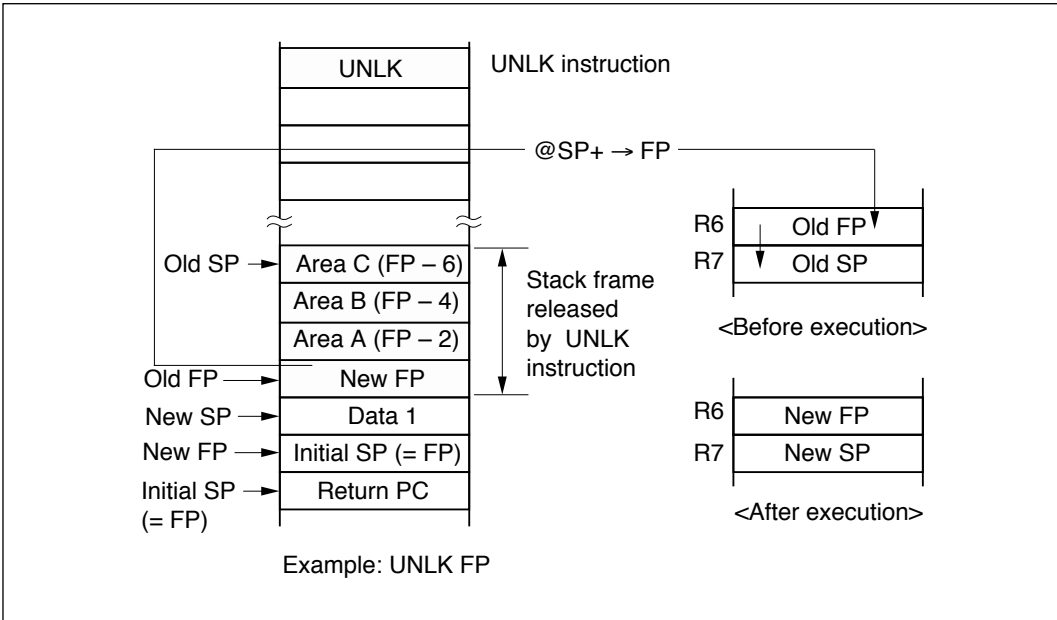

Operation: $FP(R6) \rightarrow @-SP,$
 $SP \rightarrow FP(R6),$
 $SP + \#IMM \rightarrow SP$

Stack Frame Area: Specified by eight-bit or 16-bit immediate data.

(5) UNLK Instruction (—): Releases a stack frame created by the LINK instruction.

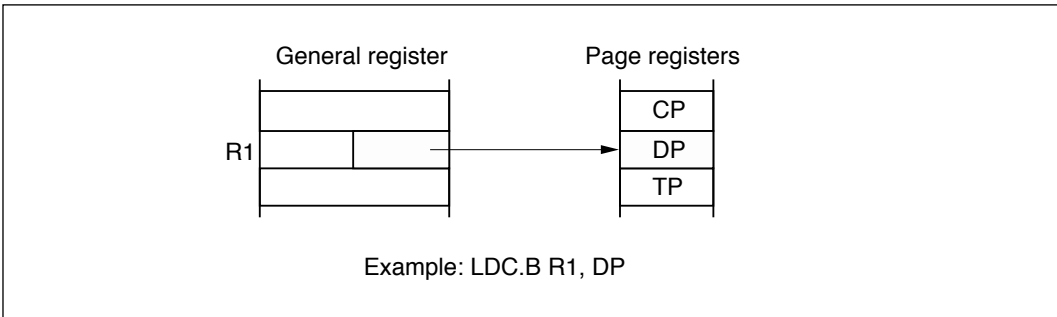

Operation: FP (R6) → SP,
@SP+ → FP (R6)

(6) SLEEP Instruction (—): Causes a transition to a power-down state.

(7) LDC Instruction (B/W): Moves immediate data or general register or memory contents into a specified control register.

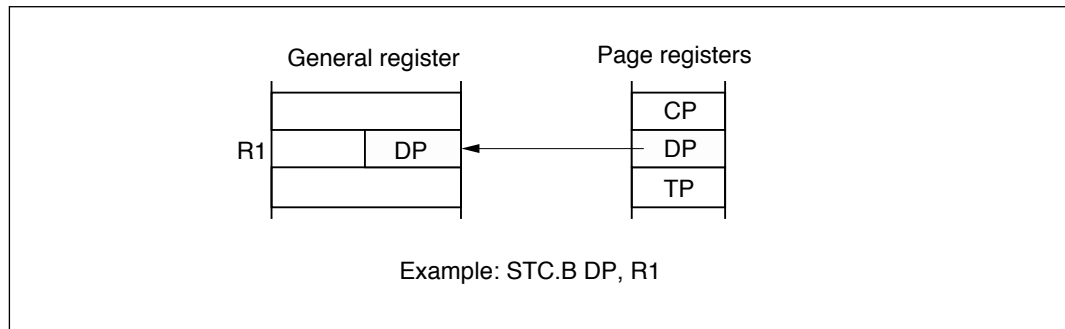

Operation: (EAs) → CR

Instructions and Operand Sizes: The operand size depends on the control register.

(8) STC Instruction (B/W): Moves specified control register data to a general register or memory.

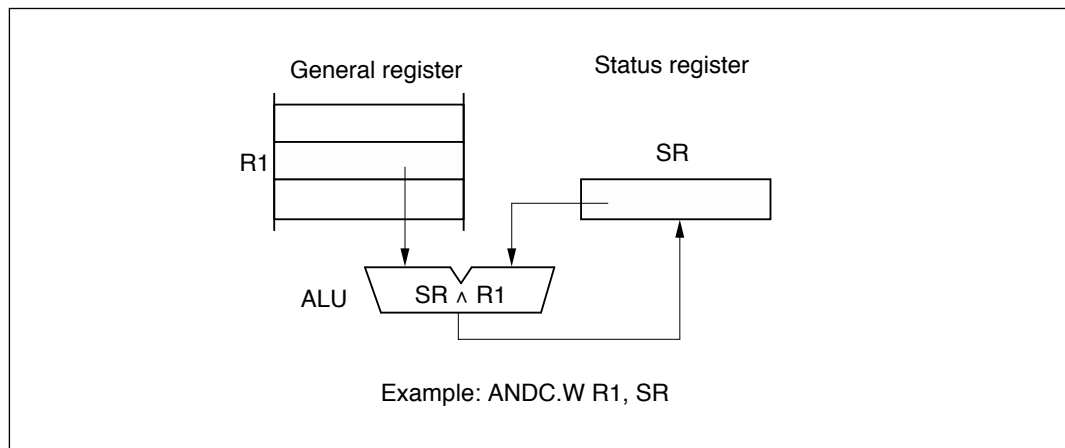

Operation: $CR \rightarrow (EAd)$

Instructions and Operand Sizes: The operand size depends on the control register.

(9) ANDC Instruction (B/W): Logically ANDs a control register with immediate data.

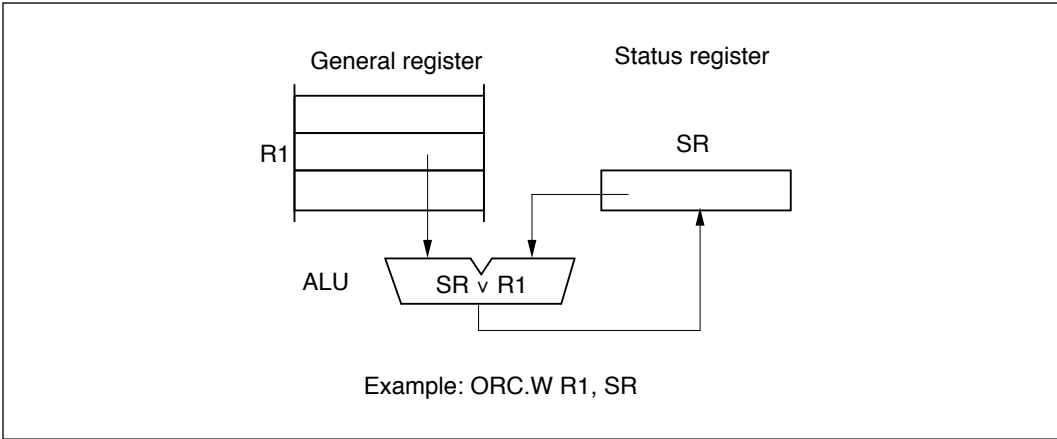

Operation: $CR \wedge \#IMM \rightarrow CR$

Instructions and Operand Sizes: The operand size depends on the control register.

(10) ORC Instruction (B/W): Logically ORs a control register with immediate data.

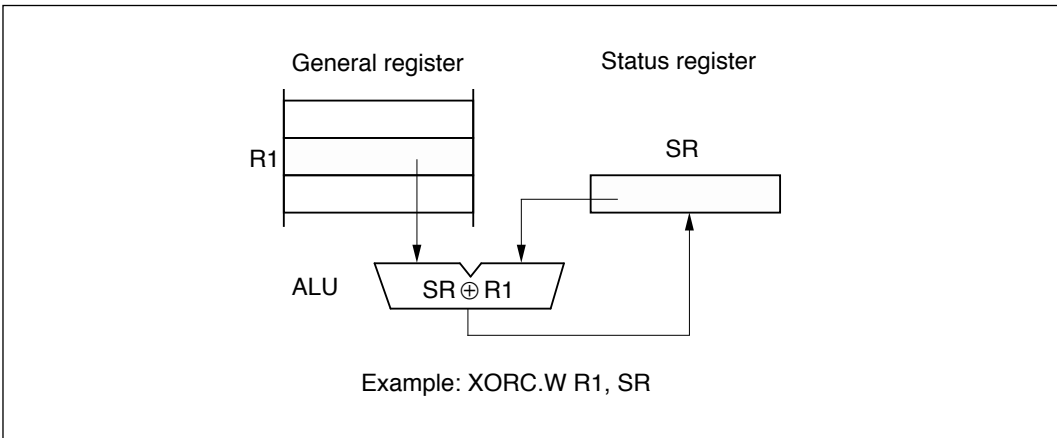

Operation: $CR \vee \#IMM \rightarrow CR$

Instructions and Operand Sizes: The operand size depends on the control register.

(11) XORC Instruction (B/W): Logically exclusive-ORs a control register with immediate data.

Operation: $CR \oplus \#IMM \rightarrow CR$

Instructions and Operand Sizes: The operand size depends on the control register.

(12) NOP Instruction (—): Only increments the program counter.

Operation: $PC + 1 \rightarrow PC$

A.5.11 Short-Format Instructions

The ADD, CMP, and MOV instructions have special short formats. The short formats are a byte shorter than the corresponding general formats, and most of them execute one state faster. Table A-12 lists these short formats together with the equivalent general formats.

Table A-12 Short-Format Instructions and Equivalent General Formats

Short-Format Instruction	Length	Execution States*2	Equivalent General-Format Instruction	Length	Execution States*2
ADD: Q #xx, Rd*1	2	2	ADD: G #xx: 8, Rd	3	3
CMP: E #xx: 8, Rd	2	2	CMP: G.B #xx: 8, Rd	3	3
CMP: I #xx: 16, Rd	3	3	CMP: G.W #xx: 16, Rd	4	4
MOV: E #xx: 8, Rd	2	2	MOV: G.B #xx: 8, Rd	3	3
MOV: I #xx: 16, Rd	3	3	MOV: G.W #xx: 16, Rd	4	4
MOV: L @aa: 8, Rd	2	5	MOV: G @aa: 8, Rd	3	5
MOV: S Rs, @aa: 8	2	5	MOV: G Rs, @aa: 8	3	5
MOV: F @ (d; 8, R6), Rd	2	5	MOV: G @ (d: 8, R6), Rd	3	5
MOV: F Rs, @ (d: 8, R6)	2	5	MOV: G Rs, @ (d: 8, R6)	3	5

Notes: 1. The ADD:Q instruction accepts other destination operands in addition to a general register.

2. Number of execution states for access to on-chip memory.

Appendix G Pin States

G.1 States of I/O Ports

Table G-1 States of I/O Ports

Pin Name	Mode	Reset	Hardware Standby Mode	Software Standby Mode	Sleep Mode	Bus Release Mode	Program Execution Mode (Normal Operation)
\emptyset	—	Clock output	T	H	Clock output	Clock output	Clock output
RD, AS, HWR, LWR	1–6	H	T	T	H	T	RD, AS, HWR, LWR
	7	T	T	T	T	T	—
P1 ₇ –P1 ₀	1–6	T	T	T	T	T	D ₁₅ –D ₈
	7			keep	keep	keep	I/O port
P2 ₇ –P2 ₀	1, 3–5, 6	T	T	T	T	T	D ₇ –D ₀
	2, 7			keep	keep	keep	I/O port
P3 ₅ –P3 ₀ P4 ₇ –P4 ₀ P5 ₇ –P5 ₀ P6 ₄ –P6 ₀ P7 ₇ –P7 ₀	1–7	T	T	keep* ¹	keep	keep	I/O port
P8 ₄ –P8 ₀ P9 ₇ –P9 ₀	1–7	T	T	T	T	T	Input port
PA ₆ –PA ₄	1–7	T	T	keep* ²	keep* ³	keep* ⁴	I/O port or control input/output
PA ₃ –PA ₀	3–5	T	T	T	L	T	A ₁₉ –A ₁₆
	1, 2, 6, 7			keep* ¹	keep	keep	I/O port
PB ₇ –PB ₀ PC ₇ –PC ₀	1–6	T	T	T	L	T	A ₁₅ –A ₀
	7			keep	keep	keep	I/O port

Legend

H: High, L: Low, T: High-impedance state

keep: Input pins are in the high-impedance state; output pins maintain their previous state.

- Notes: 1. The on-chip supporting modules are reset, so these pins become input or output pins according to their DDR and DR bits.
2. If PA5 is set for BACK output, it goes to the high-impedance state.
3. BREQ can be received, and BACK is high.
4. BACK is low.

G.2 Pin States at Reset

(1) Modes 1 and 6: Figure G-1 is a timing diagram for the case in which $\overline{\text{RES}}$ goes low during three-state access in mode 1 or 6. As soon as $\overline{\text{RES}}$ goes low, all ports are initialized to the input state. $\overline{\text{AS}}$, $\overline{\text{RD}}$, $\overline{\text{LWR}}$, and $\overline{\text{HWR}}$ go high, and D_{15} to D_0 go to the high-impedance state. A_{15} to A_0 are initialized to the low state 1.5 system clock cycles (1.5 ϕ) after the low level of $\overline{\text{RES}}$ is sampled.

Figure G-1 Reset during Three-State Access (Modes 1 and 6)

(2) **Mode 2:** Figure G-2 is a timing diagram for the case in which $\overline{\text{RES}}$ goes low during three-state access in mode 2. As soon as $\overline{\text{RES}}$ goes low, all ports are initialized to the input state. $\overline{\text{AS}}$, $\overline{\text{RD}}$, $\overline{\text{LWR}}$, and $\overline{\text{HWR}}$ go high, and D_{15} to D_8 go to the high-impedance state. A_{15} to A_0 are initialized as soon as $\overline{\text{RES}}$ goes low, and become input ports.

Figure G-2 Reset during Three-State Access (Mode 2)

(3) Modes 3 and 5: Figure G-3 is a timing diagram for the case in which $\overline{\text{RES}}$ goes low during three-state access in mode 3 or 5. As soon as $\overline{\text{RES}}$ goes low, all ports are initialized to the input state. $\overline{\text{AS}}$, $\overline{\text{RD}}$, $\overline{\text{LWR}}$, and $\overline{\text{HWR}}$ go high, and D_{15} to D_0 go to the high-impedance state. A_{19} to A_0 are initialized to the low state 1.5 system clock cycles (1.5 ϕ) after the low level of $\overline{\text{RES}}$ is sampled.

Figure G-3 Reset during Three-State Access (Modes 3 and 5)

(4) Mode 4: Figure G-4 is a timing diagram for the case in which $\overline{\text{RES}}$ goes low during three-state access in mode 4. As soon as $\overline{\text{RES}}$ goes low, all ports are initialized to the input state. $\overline{\text{AS}}$, $\overline{\text{RD}}$, $\overline{\text{LWR}}$, and $\overline{\text{HWR}}$ go high, and D_{15} to D_0 go to the high-impedance state. A_{19} to A_0 are initialized as soon as $\overline{\text{RES}}$ goes low, and become input ports.

Figure G-4 Reset during Three-State Access (Mode 4)

(5) Mode 7: Figure G-5 is a timing diagram for the case in which $\overline{\text{RES}}$ goes low in mode 7. As soon as $\overline{\text{RES}}$ goes low, all ports are initialized to the input state.

Figure G-5 Resetting of I/O Ports (Mode 7)

Appendix H Timing of Transition to and Recovery from Hardware Standby Mode

Timing of Transition to Hardware Standby Mode

- (1) To retain RAM contents when the RAME bit in RAMCR is set to 1, drive the $\overline{\text{RES}}$ signal low at least 10 system clocks before the fall of the $\overline{\text{STBY}}$ signal, as shown below, at a time when RAM is not being accessed. The minimum delay from the fall of $\overline{\text{STBY}}$ to the rise of $\overline{\text{RES}}$ is 0 ns.

- (2) When the RAME bit in RAMCR is cleared to 0, or when it is not necessary to retain RAM contents, the $\overline{\text{RES}}$ signal does not have to be driven low as in (1).

Timing of Recovery from Hardware Standby Mode: Drive the $\overline{\text{RES}}$ signal low approximately 100 ns before $\overline{\text{STBY}}$ goes high.

Appendix I Package Dimensions

Figure I-1 shows the FP-112 package dimensions of the H8/538F. Figure I-2 shows the TFP-120 package dimensions.
